NOTES OF THE WEEK.

Variation and Modification.

[Photo: Maull and Fox.

PROFESSOR I. BAYLEY BALFOUR, M.D., D.Sc., LL.D., F.R.S., V.M.H.

Regius Keeper of the Royal Botanic Gardens, Edinburgh.

Studying carefully the very vexed question of the causes of variation, which are recognised by some authorities to be, so far as present knowledge goes, inscrutable, while others consider them to be due entirely to environmental influence, it has appeared to us that it would simplify matters to recognise that variations fall really into two quite distinct categories, which we would differentiate as "sports proper" and "induced variations." To the former class must be allotted those sudden, and often wide departures from the normal type, of which there are so many examples in both the animal and vegetable kingdom, and which we may typify by the Niata cattle, the Ancon sheep, the Turnspit dog, and many pigeons in the one kingdom, and by a large number of wild abnormal ferns in the other. In these cases it must be borne in mind that not only have the first examples appeared with markedly different features from their immediate progenitors, but this difference is so thoroughly pervasive that they are capable of producing true progeny for indefinite periods with little or no tendency to reversion. This class, i.e., "sports proper," it is utterly impossible to impute to change of environment, or any known cause, they originate fully developed as regards their peculiar characters, under precisely the same environmental conditions as their immediate unmodified and contemporaneous relatives. The abnormal plants are found closely intermingled with their normal progenitors, and under natural conditions which indicate long-continued environmental stability. On the other hand, with the second proposed class of "induced varieties" there is no doubt whatever that plants when subjected for generations to checking, or, on the other hand, stimulating influences, are liable in time to alter in sympathy therewith. It is only reasonable to assume that the reproductive gemmules, adopting for the sake of argument the pangenetic theory, would participate in the effect of outside influences on the plant's development. We may indeed indicate a recognised instance of this kind of modification in the altered type of humanity seen in the United States, where pure-blooded descendants of European type have undoubtedly approached, under climatal influences, the native North American facial type in comparatively few generations. This fact establishes the possibility of inheritance of acquired characters so far as such characters are induced by environmental conditions, and there is little or no doubt that plants are subject to vary on similar lines, but, and this is the essential point of difference between the classes, only by gradation. This gradation may, however, be assisted, i.e., the gradational steps may be lengthened by the artificial stimulus of high culture, and under such circumstances it is conceivable that a sort of tension may be set up in the constitution of a plant so stimulated, which would find expression by inheritance in the progeny in the shape of marked variation. It is, however, to be assumed that in these cases the variations would be of a nature responsive to and sympathetic with the artificial environment, and to this extent the theory of sympathetic variation is doubtless justified. An instance of this kind is seen in M. H. de Vilmorin's experiments with the wild cabbage, which, in a very few generations, showed a marked and fixed approach to the highly specialised varieties known to horticulture, and, it may be observed, that all, or nearly all, of these varieties represent extra development of foliage, exhibited in various ways, the cauliflower and broccoli alone showing a variation in the inflorescence, which was probably a sport proper originally. This means that the foliage of the original weed was not only capable, as is natural, of developing more freely when manured and protected than when exposed to wild and more or less starved conditions, but that its seed shared in the increased vigour, and yielded progeny of a leafier character, and so on from generation to generation on an ever-increasing scale. In this class, therefore, we should not look for that indefinite variation or variations in all directions which Darwin considered as a part of the evolutionary scheme. It is solely induced by stimulation in a certain direction, viz., stronger growth, and naturally follows that line throughout, unless a really sportive tendency sets in, when it is quite an open question what would occur. In the fern tribe, for instance, several very dwarf varieties have originated from spores of robust forms, and this, under the stimulus of glass culture and shade, which naturally tends to increase the area of frondage. The dwarfs are, moreover, congested, imbricate, and compact, precisely such characters as the advocates of responsive variation, as the only variation arising, would impute to long-continued Alpine exposure, the exact opposite of the actual one. We have, however, now, we think, said enough to indicate the essential difference between the two classes of variation, which we submit for consideration to those interested in this branch of evolutionary study.

Professor Isaac Bayley Balfour, M.D., D.Sc., LL.D., F.R.S., V.M.H.—As Regius Keeper of the Royal Botanic Gardens of Edinburgh, and Professor of Botany at the Edinburgh University, Professor Bayley Balfour has rendered such splendid service in the cause of botanical science that it gives us exceptional pleasure to present our readers with his portrait. The son of John Hutton Balfour, who occupied the chair of botany at the Edinburgh University from 1845 to 1879, Professor Bayley Balfour displayed quite early in life a strong predilection for scientific botany, and he pursued his botanical studies with such remarkable success that in 1879, when in his 26th year, he was appointed Regius Professor of Botany at the Glasgow University. This position he occupied until 1884, when he was appointed Sheridan Professor of Botany at the University of Oxford. Professor Bayley Balfour remained at Oxford until 1888, when he returned to Edinburgh to fill the positions he now occupies. This brief statement will suffice to indicate that he has devoted a considerable period of his life to educational work, and judging from the results, Professor Bayley Balfour has achieved an immense amount of success in the performance of the duties associated with the important positions he has held at Glasgow, Oxford, and Edinburgh. In other directions Professor Bayley Balfour has shown a considerable amount of activity in the cause of science. He was, for instance, a member of the Transit of Venus expedition to Rodriguez in 1874, and in 1880 he explored the Island of Socotra, and among his other finds was Begonia socotrana, which has played so important a part in the creation of the valuable race of winter-flowering begonias that cultivators now have at their disposal. During the comparatively long period of which he has been Regius Keeper of the great national gardens at Edinburgh, he has devoted unremitting attention to their improvement, and has been so eminently successful in his work of reorganisation that their value for purposes of the study of scientific botany and their attractions to the general public have been enormously increased. Professor Bayley Balfour was one of the first sixty botanists and horticulturists selected by the Council of the Royal Horticultural Society to receive the Victoria Medal of Honour, a distinction well deserved, for both his administrative and educational work has been of immense value not only to Scotland but to the whole world.

The Study of Cryptogamic Botany.—Under the will of the late Professor Thomas Barker, the Manchester University has received a legacy of £40,000. This large sum is to be devoted to the foundation of a Chair of Cryptogamic Botany, and the provision of scholarships for assisting students in botany and mathematics in the prosecution of their studies.

Lucky Gardeners.—The late Mr. Cowan, of Ross Hall, Paisley, left legacies to Mr. Robert Pringle, the head gardener, and to each of his under gardeners. Mr. Pringle receives £10 for each year he has been at Ross Hall, and the under gardeners £5 for each year of service.

The "Gardeners' Magazine," 1908.—With the issue of December 28 last we completed the fiftieth volume of the Gardeners' Magazine in folio form, and this, while the most bulky of the series, is, we venture to suggest, the most attractive, interesting, and useful. In this opinion we are supported by the many expressions of approval from our readers, and the very large accession of new subscribers during the past twelve months. The Gardeners' Magazine, however, dates further back than half a century, for it was founded in 1833, and has therefore completed its seventy-fifth year, and is the oldest of all the horticultural journals. In making reference to these interesting facts we have no intention of dwelling upon the past history of the journal, with its unbroken success. We are now more concerned with the present than with the past, and we are desirous of specially directing the attention of our readers to the leading features of the journal during the current year, as set forth in another page. An examination of these will show that its interest, its usefulness, and its attractions will be fully maintained by an amplification of features that have in past years received a full share of attention, and that the new features will import much freshness to its pages, and greatly enhance the popularity enjoyed. It is not necessary we should recapitulate the features set forth elsewhere, but we would direct attention to the special arrangements we have made for describing and illustrating the more important of the many beautiful gardening districts in the United Kingdom. We believe that this feature will not only prove of much interest to all who are concerned with gardening, but that the many finely executed illustrations will be of much value to those concerned with the formation and improvement of garden-scenery. The present is, we need hardly say, an exceptionally good time for those interested in horticulture to become subscribers, and as we are anxious to be useful to the largest possible number, we shall much appreciate the kindness of those readers who bring the present issue before such of their friends as are not already subscribers.

White Lilac has been somewhat less plentiful than is usual during the Christmas and New Year's festivities, and has, consequently, been comparatively high in price. This decrease has been due to the weather having been less favourable in France, as in England, to the ripening of the wood. The variety chiefly grown at Vitry, near Paris, whence large supplies of white lilac are sent to Covent Garden, is Charles X., the flowers of which, when developed in the open, are rich mauve-pink. When the plants are forced in a structure from which the light is excluded the flowers become white.

Electric Plant Culture.—The electric culture installation lately set up in the gardens of the Royal Botanic Society in Regent's Park by Mr. B. H. Thwaite has been working provisionally for some weeks. A committee has now been formed to take charge of the experiments, and at a meeting held a few days since the course of procedure was arranged. The committee includes Mr. J. R. Diggle, chairman of council: Dr. W. Cooke Adams, Professor Bottomley, M.A., Ph.D., of King's College; Mr. G. Gordon, V.M.H., editor of the Gardeners' Magazine; Mr. P. H. Cragg, Mr. J. Green, Mr. J. H. Witty, Mr. Thwaite, and Mr. Bastin. A control house has been arranged, where the same kinds of plants will be grown for comparison under precisely the same conditions, but without electric light. The committee have arranged for regular observations, and the results obtained will be compared and tabulated day by day. The houses will be open so that Fellows and visitors to the gardens will have ample opportunities of seeing the work carried on in its various stages.

Royal Gardeners' Orphan Fund.—The twenty-first annual festival of this charity will take place at the Hotel Cecil on Tuesday, May 12. The president of the fund, the Duke of Bedford, K.G., has kindly consented to preside.

Potato Sets.—In the course of an address on horticultural matters at West Clandon, the other evening, Mr. Alexander Dean, V.M.H., referred to the trials of potatoes that had been made at Chessington, under the auspices of the Surrey Education Committee. Three plots were devoted to a trial of Surrey, Scotch, and Irish seed, each consisting of six rows containing twenty-six tubers. The produce from these were, he stated, as follows: Surrey seed, 91lb.; Scotch seed, 365lb.; and Irish seed, 407lb. Mr. Dean said that as yet the authorities had not been successful in assigning a reason for the great difference in the result from English seed as compared with Irish and Scotch seed, but he had little doubt that the difference in climatic condition was an important factor.

Tropical Cockroaches at Kew.—The tropical plant houses at Kew are, according to a note contributed by Mr. W. Watson to the current issue of the "Kew Bulletin," infested with cockroaches which are only prevented from doing a great deal of damage to the plants by constant trapping. At least three species are injurious, namely, Blatta orientalis, Linn., B. (Periplaneta) americana, Linn., and B. (P.) australasiæ, Fab., the second being the largest and the third by far the most abundant. Their haunts are dry holes and corners about the stages and hot-water pipes, the sheathing bases of palm, banana and pandanus leaves, and among the crocks in large plant-pots and tubs. They are in hiding during the day, but at night they come out and run or fly about among the plants, devouring flowers and leaves like rabbits. Such plants as eucharis, crinum, and alpinia, when in flower, have little chance in the palm house, where the cockroaches are most abundant; they also find out the ripening bananas and soon devour them. They are as clever as mice in scenting food and more clever in learning what to avoid in the shape of a trap or poison. Jars with a little treacle at the bottom will trap them for a few weeks, then the bait must be changed to beer, linseed oil, or sugar and water, otherwise the cockroaches cease to be attracted.

South-Eastern Counties Daffodil Show.—We are pleased to learn From Mr. F. Herbert Chapman, the honorary secretary, that the Kent, Surrey, and Sussex Daffodil and Spring Show Society is steadily increasing in popularity and strength, and regarded with much favour by lovers of spring flowers throughout the three counties that form the sphere of its activities. The annual exhibition for the current year has been fixed and will be held at the Great Hall, Tunbridge Wells, on April 15.

The Gardeners' Magazine Almanack.—With this issue we present our readers with a double-page almanack for the current year. This has been prepared with special reference to usefulness, and contains the dates of all the principal horticultural exhibitions and meetings that had been arranged at the time of going to press.

SINGLE ROSES FOR BORDERS

Both in writing and speaking appreciatively of either of the several groups of roses, it is too much the practice to endeavour to exalt the merits of the group at the expense of one or more of the others. If the desire be to direct prominent attention to the hybrid teas, more often than not a comparison is instituted between them and the tea-scented, on the one side, and the hybrid perpetuals on the other, in such manner as to endeavour to show their great superiority over both groups. They may be better for certain purposes than either of the others, but it does not consequently follow that they should alone be grown. In like manner, few writers who hold the single-flowered roses in high estimation can make reference to their favourites without endeavouring to show that double roses are so wanting in refinement that those who prefer them to the singles must be deficient in taste. On the other hand, the champions of double roses now and again declare the single roses to be so flimsy and ephemeral as to be hardly worthy of a place in the garden.

It is, in my opinion, a great mistake in directing attention to one section to speak or write of them in such manner as to suggest that the varieties included in it are alone worth growing. All sections of roses are more or less beautiful, and the best course in giving advice to budding rosarians is to describe the leading characteristics of the varieties forming the several sections, and direct attention to the purposes for which they are best adapted. With this grounding in knowledge the tyro will be able to give free play to his taste in making selections, without the risk of filling his garden with roses that are not suitable for the purposes for which they are required, or not in accordance with his taste.

As a case in point, I would mention that I have a great liking for the single varieties, and probably no one could more greatly admire the charms of a well-flowered dog rose than myself. At the same time, I do not allow my admiration of the elegance which characterises the single roses to prevent my appreciating the merits of the double varieties. Of the two groups I consider that in which the double varieties have a place is the most generally useful. There are, however, now so many beautiful single roses available that a selection should have a place in all gardens in which roses are grown to any considerable extent. The flowers of the finest of the single varieties are exquisitely beautiful both in form and colour, and present so pleasing a contrast to the double flowers as to be invariably much admired. To obtain a full measure of enjoyment from them it is not advisable to attempt the formation of a collection, but rather to have a small selection, in which none but the very best are included.

Less than twelve varieties will suffice for the majority of gardens, and I would suggest that where the garden is large enough to admit of a considerable area being devoted to single roses, several plants of each variety be grown. The single roses that, in my opinion, can be the most strongly recommended for beds and borders are the following: The Copper and Yellow Austrian briers, with bright red and rich yellow flowers respectively, are most desirable. These fine single roses are seldom seen in perfection owing to their being grown as standards, and severely pruned. Grown in bush form, with but little pruning, they make a strong growth, bloom profusely, and produce large richly coloured flowers. Belle Fleur, introduced by Mr. G. Prince a few years since, has a vigorous habit, and produces a profusion of crimson flowers; it is bright and effective, and particularly good in the autumn. Irish Beauty, Irish Elegance, and Irish Glory are three single hybrid teas, raised by Messrs. A. Dickson and Sons, of Newtownards, possessing much merit, being vigorous in growth and free and continuous in flowering. Irish Beauty has white flowers; Irish Elegance, illustrated herewith, was awarded the gold medal of the National Rose Society in the autumn of 1905, and has flowers of various shades of apricot, and orange-red buds; and Irish Glory has flowers of a pleasing shade of silvery-pink. Maharajah, raised by Messrs. B. R. Cant and Sons, of Colchester, is a very distinct hybrid perpetual with large flowers of a deep crimson hue. Mrs. O. G. Orpen, a lovely damask rose, with large and exquisitely beautiful blush-pink flowers; Macrantha, a handsome strong-growing species, with large flesh-pink flowers; Morgenrot, a distinct variety of German origin, robust in growth, and bearing a profusion of bright crimson flowers; Paul's Single White, a beautiful white variety, makes a large bush when not unduly restricted, and is extremely beautiful. Royal Scarlet, which also was introduced by Messrs. Paul and Son, is one of the most effective of single roses, the flowers being brilliant scarlet, and freely produced in clusters. Rosa sinica Anemone may be described as one of the most beautiful of single roses, but requires a wall, except in very favoured districts and on warm soils; the flowers are large, finely formed, and of a pleasing pink hue.

A BEAUTIFUL SINGLE-FLOWERED HYBRID TEA ROSE, IRISH ELEGANCE.

Rich orange-red in bud stage, and varying shades of apricot when expanded.

It may be added that the three hybrid teas raised at Newtownards are well adapted for growing in beds on the lawn, one variety in each. Viator.

Trees and Shrubs for Towns.

Our American friends are discovering the need for a careful selection of trees and shrubs for planting in towns where closely-set dwelling houses and factory make the atmosphere smoke laden. It has been found that the linden, ash, and sycamore, the Virginian creeper, wistaria and laburnum are most immune from ill effects of smoke in America.

SEEDLING CARNATIONS.

When raising seedling perpetual or tree carnations it is interesting to note the variation in colour and growth, and also the tendency of some seedlings to follow the parents in some characteristic or other, while some will show a distinct break away from either parent. It is instructive, as well as interesting, to watch progress from cross fertilisation to the flowering of the seedling, but the work requires the patience of a disciple of Izaak Walton, for there is a large element of uncertainty as to the results of one's labours, but perhaps it is this that gives zest to one's endeavours in this interesting work.

I selected the variety Mrs. T. W. Lawson, fertilising it with its own pollen, as being likely to give some seedlings of interest. From the first batch three were selected for further trial, these eventually being reduced to two, a large scarlet and a fancy variety. The scarlet variety was again crossed with a seedling from Apollo and C. A. Dana, the resultant seedlings producing several fancies, scarlets, and also whites and bright salmon colours. One of the fancies is a cream ground suffused with apricot and pink, a very beautiful blend of colour, and quite distinct from any fancy that I am acquainted with. The flowers have non-bursting calyces, are produced on long stems, and the plants come into flower quickly.

Harry Fenn, crossed with the pollen of Mrs. Brooks, gave a variety of colours, the plants generally partaking of the Mrs. Brooks habit; among the seedlings we had whites, salmon-scarlets, whites suffused with pink, cerise, and a white with markings of pink and purple—a novel blend of colour. All this batch produced flowers on long stems, and with good calyces. A seedling of two generations from Mrs. T. W. Lawson, and crossed with its own pollen gave us the greatest variety of colours, including some almost yellow selfs, but no dark colour or crimson shades. The flowers were mostly of Lawson shape and build, with good stems, and non-bursting calyces. The best, or those that showed the best points that tree carnations should possess, have been crossed again, and I am looking forward to the time when, early in the year, these seedlings will bloom.

The English variety, Mermaid, fertilised with its own pollen produced seedlings which, although not giving much variety of colour, produced much larger blooms than the parent, and a much better and freer habit of growth. The variety Mermaid crossed with the variety Daheim gave nearly all shades of pink, the only evidence of Daheim in the crosses being a stronger growth and habit. Daheim fertilised with Fair Maid pollen produced seedlings with very little evidence of any relationship with Fair Maid, but one seedling had blooms rather novel in colour, being a clear pink with short purple lines on the petals.

Seedlings raised from Fair Maid, crossed with Daheim, gave very little evidence of influence from the latter variety, all the resultant seedlings showing the characteristics of Fair Maid. A union between the variety America and Fair Maid gave seedlings of exceptionally vigorous growth, partaking of Fair Maid, while the colour and shape of blooms more resembled America.

From another cross between Daheim and Fair Maid I have a batch of seedlings to flower in the spring. Among all the seedlings flowered during the past two seasons there has only been one crimson, and this was a seedling from Daheim. Others from this batch are in bud and opening their blooms, and, so far, promise to give a greater variety of colours.

We have not yet attained to perfection in any one variety, and probably never will, but this should not deter anyone from striving after that ideal, nor yet from trying to raise another 30,000 dollar variety.

Poltimore Gardens. T. H. SLADE.

CYCLAMEN.

During the dull winter months a house filled with well-grown cyclamen is most attractive. There has been a marked improvement of late both in the colours and substance of the flowers, and as some varieties produce flower stems a foot or more in length they are very useful for cutting. The various shades of salmon, salmon-pink, and the delicate rose tints are very useful for this purpose, as they show up so well at night.

Cyclamen are by no means difficult to grow, but constant attention must be given them in their early stages if the finest results are to be obtained. Sowing the seed requires special consideration both as to the time and the manner. Many err in placing the seed pans in too high a temperature, others in sowing the seed too thickly and allowing the seedlings to become overcrowded while young. The cultivator must, in a measure, be guided by the means at his command as to the time of sowing, but it is a great mistake to hurry the small plants on during the dull months, and then allow them to receive a check just at the time when they ought to be making their growth.

We grow from five hundred to seven hundred plants annually. The seed is sown, or rather dibbled in the soil during the early part of September, the pans containing the seed being afterwards stood on the greenhouse shelf and carefully watered until the young seedlings appear through the soil. By this time the days are getting short, and the nights cold, and the pans are therefore removed to a warmer temperature of about 50 degrees at night. The plants are, however, still kept near the glass, where all the light possible at this dull season can be afforded them. About the middle of November the seedlings should be strong enough for pricking off, so they are carefully lifted and transferred to other pans or boxes, allowing them to stand about two inches apart. We consider this far better than potting them off singly at this early stage, as less watering is needed, and the plants are not so liable to damp off. There is also an economy in space, as all the room in the houses is needed at this time of the year.

By the first week in February the plants will have become sturdy, and be carrying four or five leaves. A slight hot-bed is then made up for them, the surface of this being covered with leaf-soil that has been passed through a half-inch sieve. The plants are then potted singly in small pots, and stood on the leaf-soil. The gentle heat arising from the hot-bed soon induces them to make fresh roots, and in the course of about a month they may be transferred into large 60-sized pots. If a day temperature of about 60 degrees be maintained, and the night temperature is not allowed to fall below 55 degrees, the plants will make sturdy growth. By the latter part of March many of the pits that have been used for forcing asparagus, French beans, potatoes, and the like, may not be required, so that if a slight hot-bed is made up in them, the surface being covered with leaf-soil or other material, as before advised, the plants could be transferred thereto. As the sun will by this date have attained greater power, the plants will need shading in bright weather for a few hours in the middle of the day, but the material used must not be too heavy, otherwise the foliage will become flabby.

When the 60-sized pots are filled with roots the plants should have their final shift, this time into those of 32-size. The nights will now be warmer, and ventilation may be afforded at all times, provided the weather is favourable. Here the plants have a slight bottom heat from the time they are first potted until they come into bloom, but at no time is there a close atmosphere. Some advocate standing the plants on a bed of ashes, but we prefer the fermenting material covered with soil, over which we dust a good sprinkling of soot each time the plants are moved. In this way we are never troubled with worms stopping up the drainage.

By the end of September or early in October the plants are in bloom, and they are removed to the greenhouse; they are sturdy, and have their pots well filled with roots. Many of them carry from fifty to sixty expanded blooms, and others developing so as to keep up a succession of flowers until the following March, when they must give place to other subjects.

Soil, potting, watering, and temperature all play such important parts in the production of plants that it is necessary to consider each separately. The staple here is a stiff loam bordering on clay, therefore to this is added amply half-decayed leaf-soil and sufficient old mortar rubble and sand to keep the whole sweet and porous; in this the roots ramble freely, soon reach the sides of the pots, when, if care be taken in watering and a suitable temperature is afforded them, growth is rapid and healthy. It is astonishing the quantity of flowers a well-grown cyclamen plant is capable of producing, and the length of time the flowers will last if kept in a suitable temperature and a fairly dry atmosphere.

The varieties of cyclamen are now very numerous, and the strains so much improved that one would scarce think they were the same as those grown half a century ago. There is the feathered form known by the name of Pioneer, of which there are various colours; the crested forms, the Papilios, or butterfly forms, and the giganteum strains. We have a cyclamen with a deep canary coloured cresting, the lower portion of the petals being of a clear ivory-white, while others are beautifully shaded with pink or salmon. These, however, appear to require a rather higher temperature to expand their flowers properly in, therefore should be grown in the warmest portion of the house. The markings on the foliage of some cyclamen is so remarkable that even were no flowers produced they are worthy of cultivation for this alone, but having extra fine flowers they are doubly attractive.

H. C. PRINSEP.

Buxted Park Gardens.

Another Sweet Pea Daniel Come to Judgment.—This time it is Mr. Horace J. Wright, late secretary N.S.P.A., and now firmly established in business as a seed merchant, with a marked penchant for sweet peas. In his recently issued catalogue—a publication unique in its way, and of much artistic and other merit—Mr. Wright recommends sweet pea growers to "use 7lb. of superphosphate per square yard." Now, what can this mean? Does it mean that Mr. Wright is also opening business in artificial manures, or is it simply a joke on the part of the printer man? I strongly suspect that it is a case of "sparing the rod and spoiling the yard," but perhaps an explanation will now be forthcoming.—E. J. K.

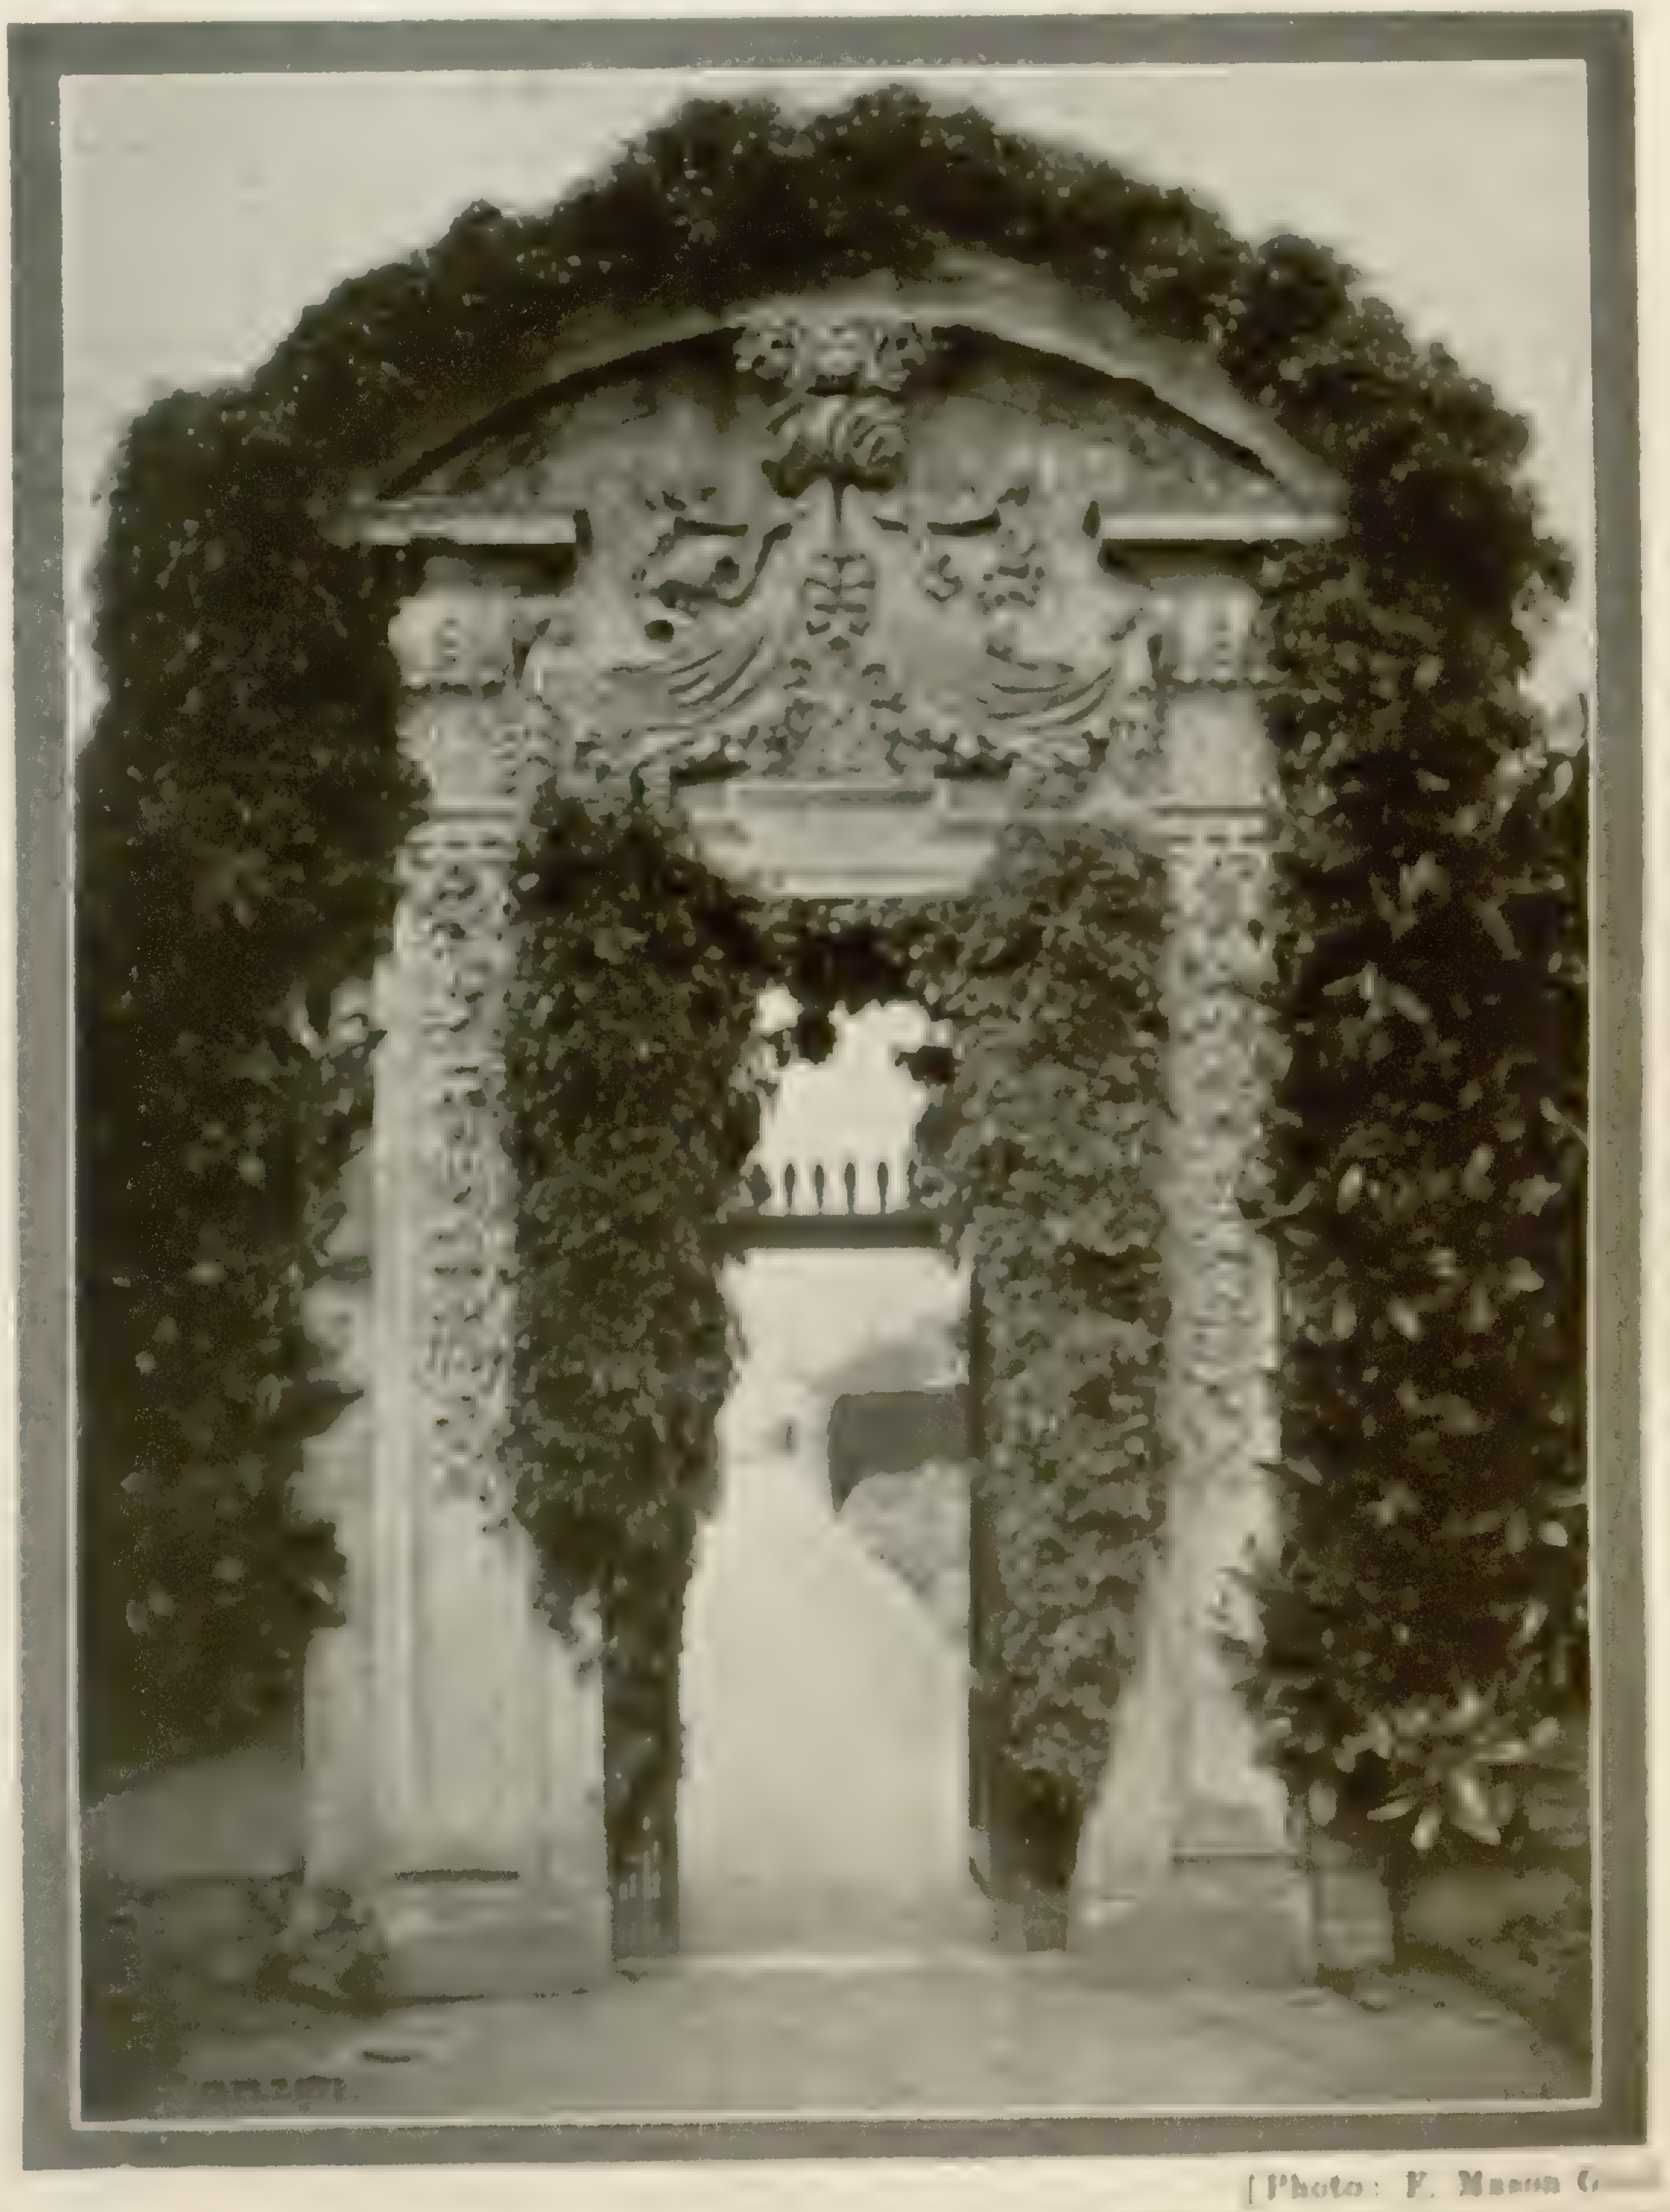
GARDEN GATES.

Throughout the whole history of architecture the part played by the door, or, to speak more broadly, the entrance, has been one of the utmost importance. Great architects of all nations and civilisations, from those of ancient days to our own times, have expended upon the doorway their highest efforts, and have contrived often to make it a thing of beauty and meaning. It is, however, to other nations than our own that we must go to find it taking the most prominent place, as do the marvellous gateways of China and Japan. Here we are too apt to regard the doorway as merely a hole in the wall or hedge through which to proceed to the other side, and too often fail altogether to grasp either its meaning or its many possibilities.

The door, at the same time the warder of the secrets within and the friend through whose offices we gain access to them, should emphasise the importance of its position, and suggest in its character and construction the nature of those secrets; in fact, that it should embody the feeling of that which it guards, cannot be too strongly insisted on. It should strike the keynote of the subsequent harmony, and (like the overture of an opera) create for us the atmosphere into which we are presently to step. Who has not felt, at some time or other, the influence of the "doorway." The welcoming, friendly aspect of some— the forbidding gloom of others, through which we effect what we feel to be a grudgingly-accorded entrance. Yet how few appear to realise that those few moments spent beneath the frown of an inhospitable doorway may strike a feeling into the heart of the visitor far removed from that intended by the host. Let your door be a hospitable one, setting forth the kindly feelings of those within. Let it wear a look of welcome for the wished-for guest.

From the first sight of an entrance or approach to a domain of either noble or simple dimensions we usually take our cue as to what lies on the further side, and, in these latter days, when the cult of "the garden beautiful" is striven after in an ideal manner, to an extent hitherto unknown, it behoves one and all to see to it that the threshold of the pleasaunce is suitably and artistically ordered. What a delightful thing it is to stand before a quaint old gate of some Tudor design, carried out simply in oak and silver-grey with age, and to picture to oneself flagged paths, smiling borders, an old sun-dial, and quaint stone seat, all redolent with the perfume of lavender, and then to open the same door and find the conjured picture true. How much more grateful one is for the peace of the old garden, because of the introduction effected by the gate, and how disappointed one would have been had the doorway proved an invitation to an imagined promised land that had no existence except in our thoughts.

One pauses, involuntarily, a moment before stretching out the hand that will make the unknown ours, to sketch in our mind's eye a picture of what we feel should be on the further side, basing our view, unconsciously perhaps, on the idea which the gate and its setting suggests to us. For the formal style of gardening which it has become the custom to term the Italian garden, nothing can be more fitting than a handsome gateway, such as that at Swallowfield Park, near Reading, of which an illustration is given herewith, or some specimen of beautiful wrought-iron, of which exquisite gates are now and again to be seen. For the wild garden such an entrance would be totally out of keeping. Here the structure should be of wood, and simplicity should be the dominant note. What is known by the misleading title of "rustic work" should be absolutely prohibited, since this is overlaid with such a profusion of trivial detail, in the shape of short, curved sections of wood, either with the bark adhering, or barked and varnished, that it effectually banishes all sense of repose from its surroundings. The appearance of the gate leading to the wild gardens should be unpretentious, and should denote durability. A modest wicket, set perhaps in an ivied wall, jewelled with bright green moss, with a colony of tall foxglove spires and a spray of flowering eglantine showing on the further side, just sufficiently hinting of what lies beyond whets one's curiosity still further.



[Photo: F. Mason Good.

FINE GATEWAY INTO FLOWER GARDEN, SWALLOWFIELD PARK, READING.

For the kitchen garden the gates should, if possible, harmonise with the particular section into which they lead, but, if they are visible from the garden proper, fine wrought-iron work may be used with advantage. The Queen's Vine-gate at Sandringham, with its beautifully modelled bunches of grapes and vine foliage, affords an excellent example. Where the kitchen garden lies apart nothing can be more pleasing than wooden Elizabethan doors, leading where the wide herbaceous borders, bright with many old-fashioned flowers, edge the broad walks and the sweet scent of herbs fills the air.

Of the inartistic qualities of the ordinary villa gate we are all too painfully aware. On its brightly-painted surface often appears some such title as The Cedars, when the only tree in sight is a miserable, stunted specimen of the araucaria in the middle of the grass plot. Still more ludicrous are the massive iron gates, hung between stone pillars surmounted by rampant lions, with no other moral support than a few feet of neat drive, terminating in a "desirable villa residence."

S. W. FITZHERBERT.

Hippeastrums. — The hippeastrums are of immense value for flower production during the earlier months of the year. A batch of these may now be selected for starting into growth, choosing those bulbs which have been thoroughly ripened and have been given a long season of rest. Previous to starting, the bulbs should be thoroughly examined, as there is always a certain quantity of decayed and decaying material at the crown. If not already done this should be carefully removed, as it often contains the insects or the larvæ of insects which injure the plants. To make certain there is no insects in hiding, the bulbs should be washed with a weak solution of soft soap, to which a little sulphur has been added, after which, when the bulbs are dry, they may be dusted with tobacco powder. Keep a watchful eye on those still at rest, as the crowns of the bulbs are easily injured by damp; not only does this apply to hippeastrums, but to all other bulbs and tubers which are stored and are at rest. In the house in which amaryllis are resting a temperature between [illegible] and [illegible] degrees, and a dry atmosphere should be maintained.—B. CROMWELL.

ROSE COLOURS.

The subject of rose colours is seldom, if ever, sufficiently considered; we find pinks of utterly different shades grown closely together in beds and borders, carmine-blooming climbers proudly nailed to red brick walls, and, alas! scarlet pelargoniums used, summer after summer, beneath crimson standard hybrid perpetuals. Is it true that English men and women have no sense of colour? I trust not. Rather is it that rose lovers become so enthusiastic over the beauty of different varieties that they forget, or ignore, the fact that individual perfections can destroy one another's loveliness when juxtaposed.

To take, for example, two roses that positively "shriek at each other," as the French say—L'Ideal and Reine Marie Henriette; here we have two exquisite flowers, of rarely delightful tints; use either of these roses by itself on a lawn, massing white violas beneath, and the eye of any artist will be grateful. Use either up the walls of a white brick or stone house, or to cheer the leaden surface of a gray building, and every ray of sunshine will linger lovingly on the blossoms that are warm-tinted already. I once saw a garden in which a Reine Marie Henriette rose grew luxuriantly up a square-sided white-painted wooden pillar, encircled for a yard's space by a rockery mound that concealed the rose's base; the rockery was itself encircled by a round pond, or white stone basin of water, where water lilies of pink and white flourished, and beside which rose arrowheads, foxgloves, rosy phloxes, and white spiræas, herbaceous and shrubby. The rose was grandly shown off by these surroundings.

Then, again, no artistic vision will be satisfied to rest at once upon both yellow and apricot, or buff roses: the two latter may safely be combined with any others of true copper tint, but clear yellow, be it of the lemon or amber shade, light or deep, will always make the apricot hues look lifeless, dull, and "muddy." By the bye, maroon roses, toning to black-purple, such as Sultan of Zanzibar, Xavier Olibo, etc., are most harmonious with apricot ones of the Madame Falcot type. Even white roses need careful placing. I remember the funereal appearance of a gray stone house over which climbed a rampant Aimée Vibert, and in whose front garden a cedar tree cast depressing shade. Not until plenty of golden euonymus bushes, variegated vincas, and clumps of Solidago altissima had been added to the borders, and a crimson Longworth Rambler and an Ards Rover had been trained up the walls did the dwelling lose its cemetery-suggesting gloom. Ards Rover was chosen advisedly, because the house faced east, and this hardiest of hybrid perpetuals was to be relied on, even under this misfortune, to blossom well on through autumn.

The common error in planting pink roses is, of course, the mingling of salmon colours with the pink that used to be called "carnation." La France is a most refined shade, yet contains bluish shadings that make it spoilt utterly in effect if a salmon, cerise, or coral-pink rose is beside it; with deeper pinks, such as Marie Verdier, or Paul Neyron, it does not clash, though personally I consider it dulled by their greater brilliance. Surely a rose of very delicate colour should have that beauty shown off to best advantage? La France, among white roses, is able to win highest appreciation.

Many of the old-fashioned crimson roses have the disadvantageous habit of turning purplish as soon as opened; there are innumerable modern scarlet-carmine varieties that bud, bloom, and even fade without doing this, and these should be chosen in preference. I may just mention John Stuart Mill as a magnificent clear red rose, and Tom Wood as one in whose petals the deepest shadings to the red are brown rather than bluish.

Nature can, however, do wonders in blending tints; of this the popular hybrid tea Madame Abel Chatenay is an example, for the petals are a charming combination of deep salmon and carmine-rose.

M. H.

REX BEGONIAS.

Since the introduction of Begonia Rex, which is a native of Assam, and was much prized on its first appearance, many very fine varieties and a few hybrids have been raised, and each season varieties more beautiful and noble than their predecessors are introduced. Nevertheless, for some unaccountable reason, these begonias do not gain the admiration they deserve; but as all plants have their ebb and flow of favour, we must await the turn of the tide.

Although the Rex begonias can be, and often are, grown charmingly in pots, it is when planted out in a naturally and artistically formed rockwork, associated with ferns, which add grace and elegance to their colour and beauty, that they are seen to greatest advantage. The broad leaves, distinct and handsome, beautifully nerved in the one; bright rose, silvery-white associated with rich carmine in another; elongated, laciniated, thickly bespangled with bright crimson hairs over a broad silvery zone in yet another, inadequately describes these ornamental begonias.

My object, however is not to dilate on the beauty of these begonias, but to give a short account on their successful culture as rock plants. Their propagation is a very easy matter; they strike easily and freely from cuttings; portions of the leaves also root readily, and this is the method more generally employed, as a number of plants can be raised from one leaf.

Any time during the summer, from May onwards, is a suitable time for increasing stock, choosing leaves which are firm, as these will not damp off quickly. Pots or pans well drained, and partially filled with a mixture of peat, leaf-mould, and sand, with half an inch of silver sand on the surface, should be prepared. Portions of the leaves, each about an inch square, and a part of the rib in it, should next be inserted in the soil to one-third their depth below the surface. Only give sufficient water to just moisten the sand, for if too much is given there is a liability to damping. Provide an ordinary stove temperature, and place the pans on a shelf away from the range of the syringe, where they are lightly shaded. In a month's time they will be rooted and throwing up shoots from the base.

When well established pot each plantlet in light sandy soil, and when well rooted in these pots they can be safely planted out in their permanent quarters in the fernery, along the sides of the corridor path, or fronting the stages of the plant house and conservatory.

Although of easy culture some little consideration must be given in choosing a position for planting out. Shade is beneficial when the sun is powerful, but too much shade, with insufficient air, causes long flabby growth, and reduces the beautiful colouring. When arranging the plants in the fernery give the shadier positions to the ferns, planting the begonias in the light and open spaces. The pockets in which they are to be planted should be drained, and filled with compost similar to that in which they are growing in pots. Plenty of space must be allowed as they are quick growers. During the growing season well supply them with water, and syringe them overhead each day, though this is best done in the afternoon, when the house is closed.

When once established these begonias will last for years, but it is necessary either to replace them at intervals with young stock, or the old plant must be lifted and replanted in fresh soil, removing at the same time such of the old stems as are not required.

The flowers of some varieties are in themselves handsome, and freely produced. The different kinds offer an excellent means of practice for the young hybridist, as they cross freely, and very little difficulty is found in raising seedlings.

The light silver and white foliaged kinds give an elegance in the fernery unsurpassed by any other plants. They are suitable to varied temperatures, from the heat of the stove to that of the greenhouse. Insects, as a rule, are of little trouble, and thrips, which sometimes attack the plants, can be kept under by frequent syringings.

The original Rex variety, which has a bright green ground banded with white, is now easily surpassed in beauty. A few of the best varieties are: Arthur Malet, bright red with silver sheen, midrib and veins purple; Comtesse de Montesquion, delicate silver foliage, a beautiful variety; Gemmatum, pea green, reddish-brown veins, shot with rose; Lady Annesley, silver surface, centre blue, with broad silver-grey zone; Mrs. F. Sander, a very beautiful variety, velvety chocolate-brown, silver-white margin, suffused rosy-crimson. Other desirable varieties are Conspicum, Madame Schwarz, Prince Mallenstein, Princess Charles of Denmark, President Deviolaine, punctatissima, and Marie Louise.

W. H. CLARKE,
Aston Rowant, Oxon.

Forcing Freesias.—It cannot be too widely known that freesias must be grown in a comparatively cool house to obtain the best results from them. Any attempt at forcing is generally attended by weak and elongated foliage and an absence of flowers. An ordinary greenhouse suits the plants well, and if they are kept near the light nice dwarf floriferous stuff is assured. I remember a traveller for a well-known firm of nurserymen once telling me that he had been sent off, post haste, down the country to inspect a large batch of freesias, which an excellent customer had quite failed to flower. On his arrival he found the plants in a cucumber house—and the mystery was solved. Fortunately, he had taken a dozen well-bloomed plants with him, and these convinced the customer of the error of his ways.—E. J. K.

Potting Old Spiræas.—The man who, instead of throwing spiræas away after forcing them, planted them out in a spare plot in the kitchen garden, laid by a very valuable reserve, which may now be drawn upon. These home-grown spiræas are often quite good enough for conservatory decoration, but when any doubts are felt on this head, they may go into old rhubarb pots, tubs, or boxes to give cut flowers and foliage. Those who have much decorating to do in spring know well how valuable spiræa foliage then is; the flowers of bulbs are forthcoming in thousands, but many bring no foliage with them. I remember once, when foreman, horrifying the chief by packing a corner of one of the vine borders with old spiræas—but the vines suffered no harm, and the spiræas gave heaps of flowers and foliage which we could make raids on as desired.—E. J. K.

TRESCO ABBEY; ISLES OF SCILLY.

THE ISLES OF SCILLY.

The Gardens of the Hesperides.

About forty miles west of Penzance and some five and twenty miles west of Land's End there lies, on the bosom of the broad Atlantic, a group of about a hundred and fifty islands of varying size, collectively known as the Isles of Scilly. Rugged and rocky they nevertheless yield a wealth of flowers every season, contributing thereby in no small measure to the pleasure of many thousands in the populous centres of England.

They are of entrancing interest, these Western islands. Lovers of Ancient Greece will remember them as the Hesperides, and students of Roman history will not forget, they are the Siluræ Insulæ, while those who find a keen delight in legend and romance—and who does not?—will know full well that the Isles of Scilly are but the remains, the peaks, so to speak, of that wonderful land of Lyonnesse that sank beneath the wave at the bidding of Merlin and engulfed the armies of Mordred.

To the horticulturist whose time is chiefly spent in and around London, amid the greatest rush and bustle of modern life, the Isles of Scilly offer a very hearty welcome. Although one may stay at St. Mary's for four days without any possible chance of a letter or a newspaper from the mainland, there is no need to be dull. The only communication with the great world may be a telegram from Covent Garden, posted up in a window in Hugh Town, giving the current prices of daffodils and suggesting that there is a demand for larger supplies of Scilly White, Soleil d'Or, Emperor, or some other of the several varieties so extensively grown wherever there is room or sufficient soil to cultivate them.

"Scilly's Rocky Shore."

Despite their rocks, and in addition to their romance, the Isles of Scilly are particularly fortunate. They lie full in the way of that branch of the Gulf Stream that does so much for us as a country. They have an equable climate, and, but for winds, a very genial one also. Winter, in the Scillies is a period of time, not a distinct season of the year, for spring merges into summer, a long summer into autumn, and autumn into a very early spring. The light is clear, and the air sweet and invigorating, indeed, a short sojourn in the Scillies is as good as a sea voyage, without its attendant evils, once you get there. Unfortunately not a few who cross from Penzance to see "the flowers that bloom in the spring" are sorry for themselves, even before the Wolf Light tells that half the journey is done. There is no doubt at all that the prospects of mal de mer keep many people from visiting the Scillies, were it not so then Baring-Gould's words would soon become true; he writes, "with its amount of sunshine, with its equable temperature, and its air charged with ozone, I believe Scilly will be the sanatorium of the future."

Crossing to Tresco Abbey.

For myself, as mal de mer has not hitherto claimed me for a victim, I borrow a line from Dr. Watts, and say of the Scillies:

"I have been there and still would go."

When crossing during a rather dirty passage last spring my only companion on the bridge was a gentleman whose knowledge of the islands is both broad and large; his kindnesses were many, and in his position of agent to T. A. Dorrien-Smith, Esq.—the Lord of the Isles, Mr. Maggs was able to afford me considerable information and facilities.

The largest of the Isles of Scilly is St. Mary's, and it is the residential and business centre of the Archipelago, and it is here that one is landed from Penzance. A trip to either of the other islands means another voyage. There are boats in plenty, and plenty of handy, skilful men to ply them, but even when the trip is only across the piece of clear water that is sheltered by the islands of Samson, St. Mary's, Bryher, Tresco, and St. Martin's, there is no fun in the prospect when the weather is so rough that the fishing fleet lies sheltered behind the pier in St. Mary's harbour. But one night the fishing fleet disappeared, and the next morning was sufficiently promising, so, in charge of Tom Jenkin, we sailed across the intervening two miles in almost record time. The "we" consisted of my namesake, of cypripedium, nepenthes, and Penang fame; an Anglo-Malayan friend who came from Carlisle; a keen amateur horticulturist and his wife, from the borders of Epping Forest; two ladies from far off Kimberley, and the writer all anxious to see the horticultural wonders and treasures of Tresco Abbey.

In the absence of T. A. Dorrien-Smith Esq., we were welcomed by his head gardener, Mr. John Jenkin, whom the Lord Proprietor had kindly asked to show us everything himself, personally. And here I may state that a large portion of the Tresco Abbey Gardens is always open to the public, Sundays excepted, and at one entrance there is a notice as follows:

To the Garden.

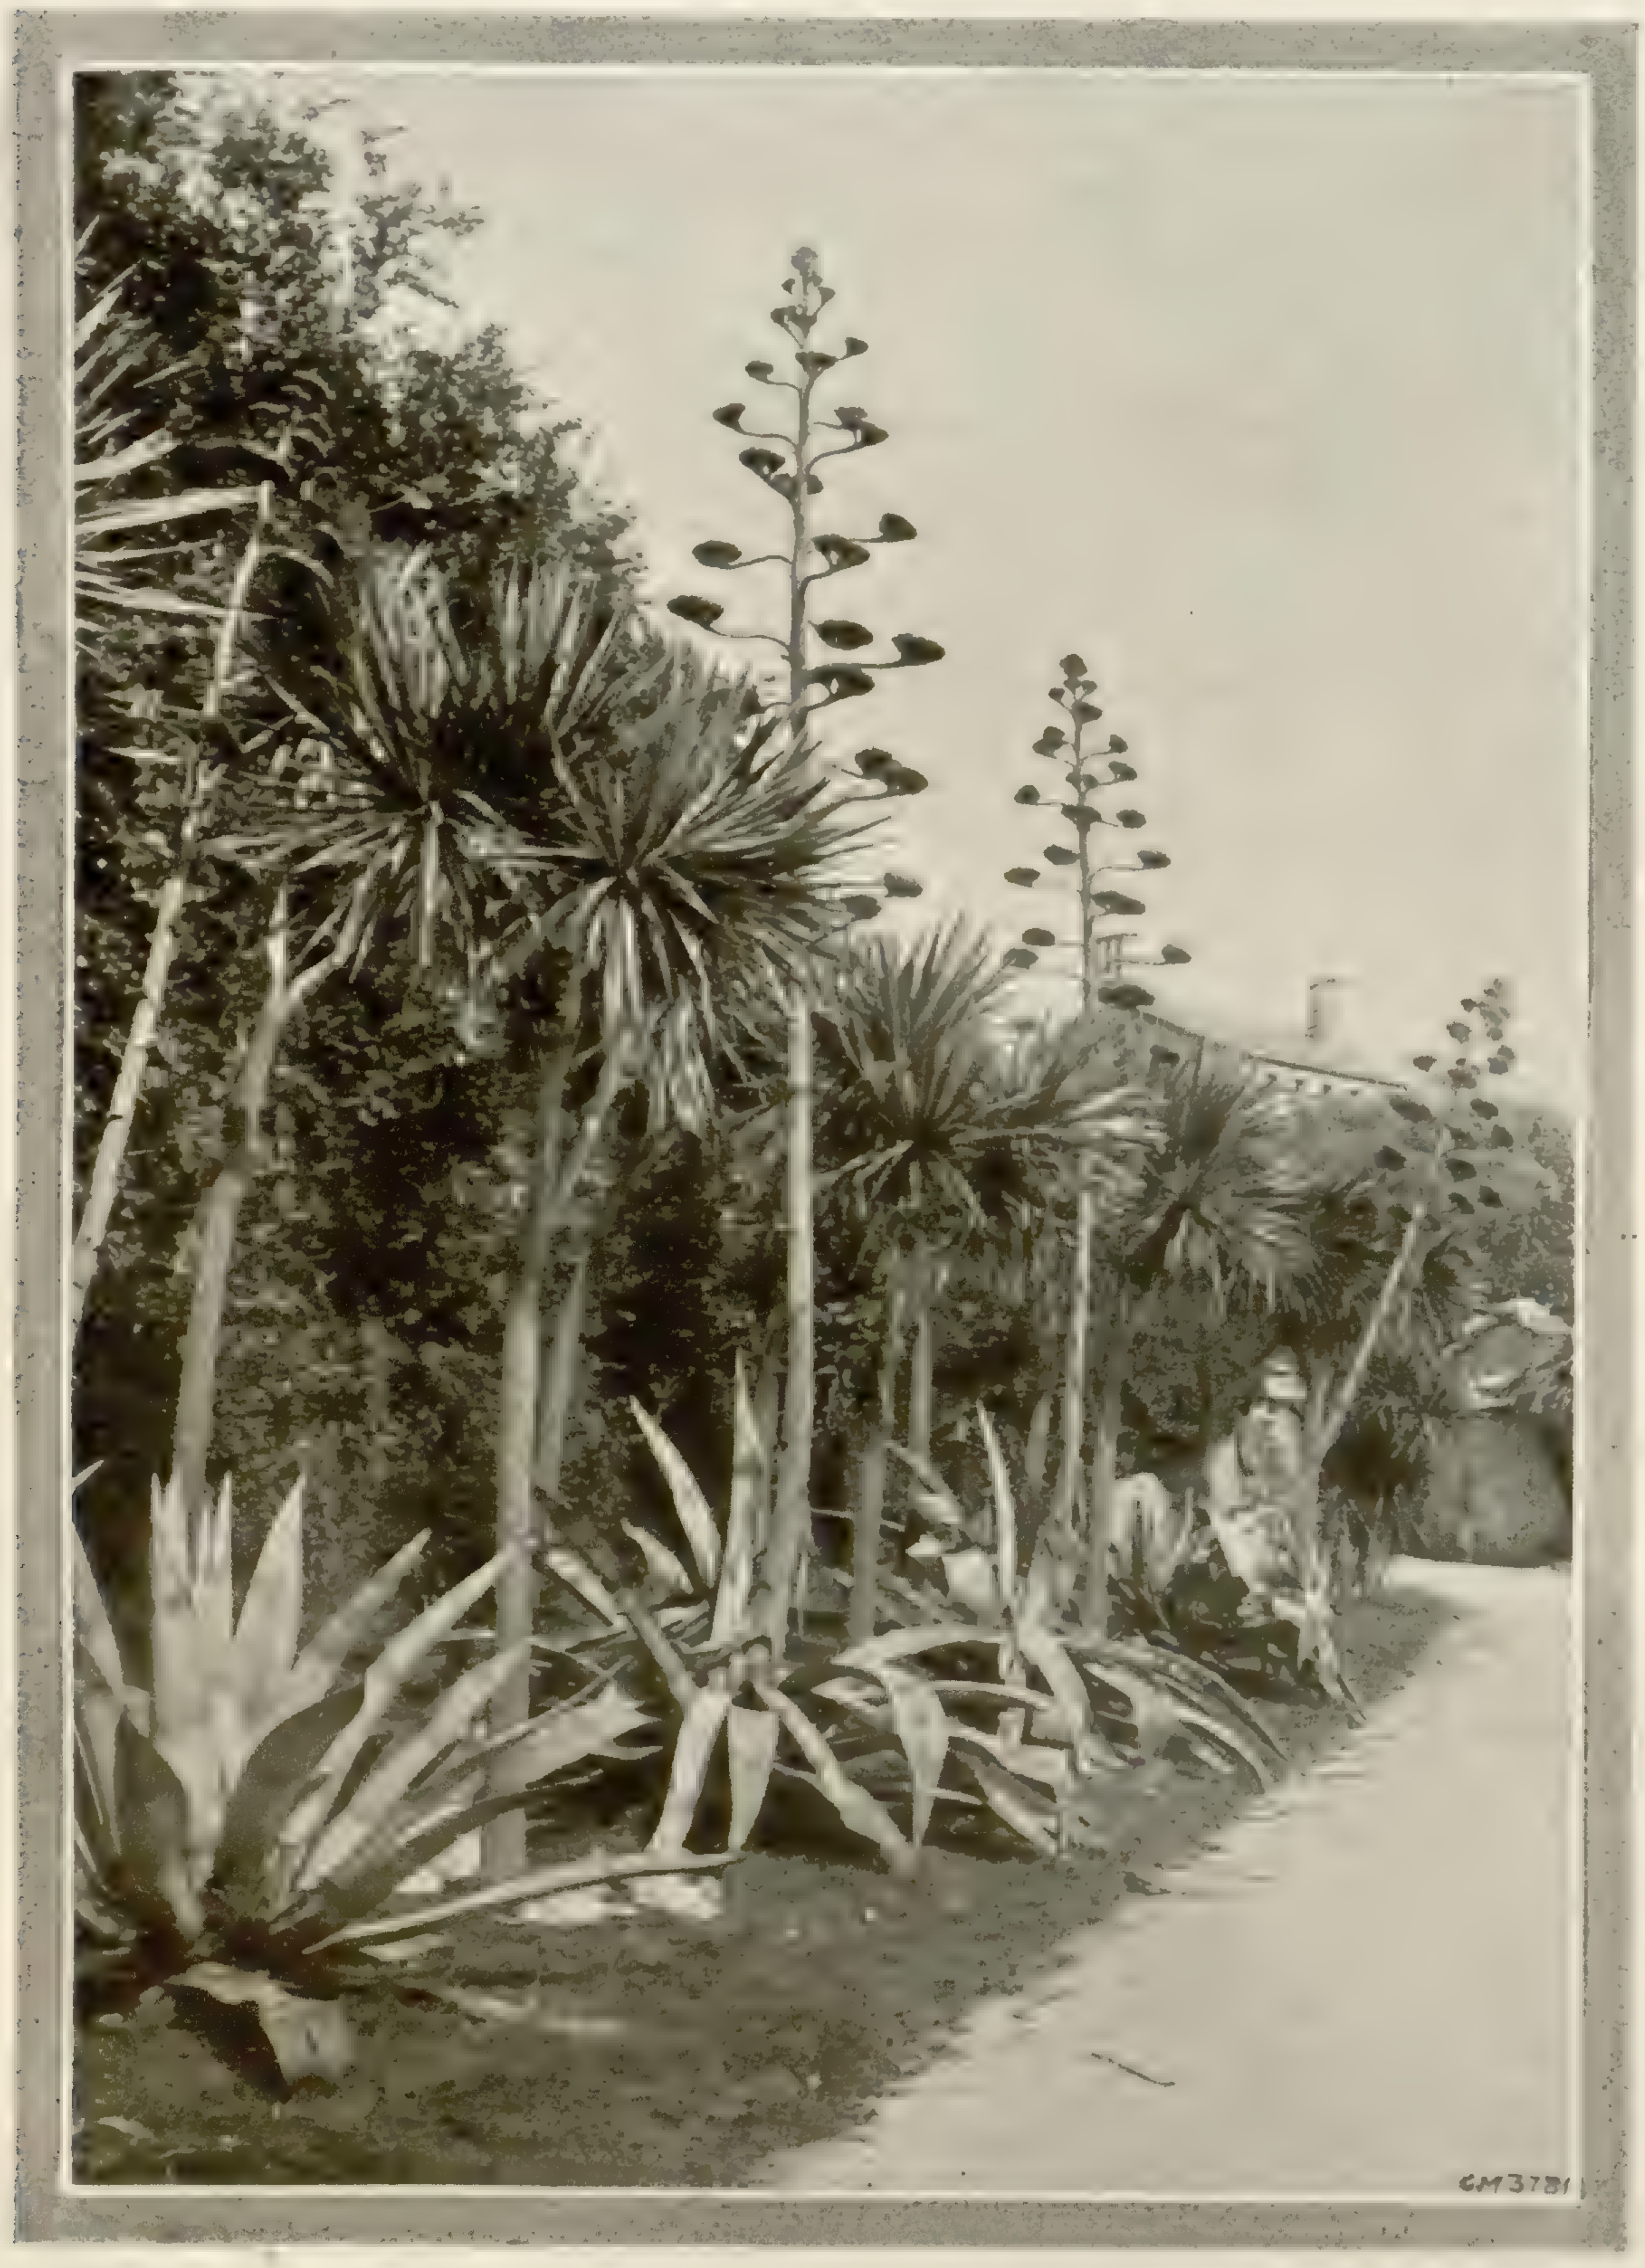
All persons are welcome to walk in these gardens, but are requested to keep to the main walks, and not go up to the house nearer than the under terrace in front, and to abstain from picking flowers or fruit, scribbling nonsense, and committing such like nuisances.

Enter then, if it so please you, and welcome.

N.B.—The gardens are open (for the islanders) from 2 to 5. Children must not come by themselves.

Chains, bars, or round stones mark the walks which are not to be used."

After signing the visitors' book one passes on to view the tennis lodge, an interesting building with its front supports consisting of figure-heads of old wooden ships that have been wrecked on the islands. They represent ships of many nations and of many sizes.



TRESCO ABBEY: PART OF THE AGAVE WALK.

Tree Ferns and Palms.

Close by one has the first real suggestion of the great interest this fine garden contains. In a sheltered opening amid big pittosporums is a colony of tree ferns, chiefly Dicksonia antarctica, Cyathea dealbata, and Alsophila australis, with masses of the low-growing Lomaria magellanica, and big specimens of Asplenium Nidus-avis. Hard by is Chamærops humilis, Corypha australis, big masses of the variegated New Zealand flax, and such rare conifers as Podocarpus andina, and the strong growing P. Totara, as well as the elegant Araucaria Bidwilli. The only shelter the tree ferns and palms receive is a screen of coarse tiffany strung from tree to tree along the windward side during the early spring. Indeed, the wind is the only trouble at Tresco, but the Island of Bryher to the westward breaks the fury of the west and south-west gales, and the higher ground on the Island of Tresco, planted with pines, curves round the back of the gardens and affords kindly shelter. In addition, hedges are planted wherever a wind break is needed, and these hedges are chiefly of Escallonia macrantha and Berberis Darwini, both evergreen and both beautiful when in flower.

Metrosideros robustus, quite a good sized tree, must be a blaze of glory when it carries hundreds of its flaming bottle-brush spikes of flowers in July; it is perfectly at home. Its near companion is Edwardsia microphylla, the New Zealand laburnum, rising 30ft. high, and bearing, the first week in April, a profusion of its yellow flowers. Another interesting shrub in full bloom at the same time is the Californian Nuttallia cerasiformis, bearing a plenitude of drooping racemes of small white flowers. The Tasmanian shrub Anopterus glandulosus, with rose-tinted, lily-of-the-valley-like flowers was of more than passing interest because it is rarely seen except as a greenhouse plant, but almost every step of the way during a delightful tour of the Tresco Gardens reveals plants that are seldom seen outside Kew, Cambridge, or other botanical institutions. Here is Erica codonodes 20ft. high., and Correa magnifica, and C. Brilliant, with their dazzling flowers taking quite an ordinary position in the borders.

Rock Garden and Agave Walk.

The gardens at Tresco Abbey occupy a crescent-shaped sloping site, with the Abbey on a rocky eminence that rises a little beyond a fresh-water lake. The Abbey is built of stone, and is set in the midst of a natural rock garden that has been improved by art. On what may be called the garden side of the house the rocks are piled up in great masses, and between them succulent plants of many kinds find a comfortable home; indeed, I doubt whether anywhere in the United Kingdom one could find such great breadths of species and varieties of gaily flowered mesembryanthemums, such masses of Aloe arborescens, and such big opuntias. Aloe ferox, A. ciliaris also do well, but to give the names of half the succulent plants that are so evidently at home here would be to compile a lengthy list. In May and June the mesembryanthemums alone would be worth going to Tresco to see.

The Agave Walk runs along one of the upper terraces, and its double row of Agave americana and A. a. variegata, all giant specimens, provide a scene that is unique in the British Isles. The plants are never protected, but they thrive amazingly. Mr. Jenkin says that over a hundred specimens have flowered during the past twelve years. All these have been replaced for, as readers are well aware, when Agave americana blooms it dies in the effort. But there is always abundance of stock from which to draw to fill up the gaps thus made. Formerly the terrace steps, crowned with a figure head of Neptune, were adorned with big agaves, but this is not so now.

The Old Abbey Garden.

Within the Tresco Gardens are the remains of the ancient Abbey of St. Nicholas, at one time an important religious establishment attached to the monastery of Tavistock. In this enclosed spot there remains but a couple of arches of the ancient building, but there are gravestones to show that even in comparatively modern times the little burial ground was used by the islanders. Now a splendid old dracæna, many branched, rises majestically and each year it flowers abundantly. Near by, as seen in the picture, is a plant of the rare Dracæna indivisa vera, with very broad leaves. Masses of Agapanthus umbellatus adorn this spot, and other interesting subjects are the Belladonna lilies, antholyzas, clivias, irises, and others of somewhat similar character.

Another enclosed garden close to the old Abbey ruins is a paradise for the plants grouped under the rather comprehensive title of Cape Bulbs. Ixias are a great success, and nerines, vallotas, babianas, sparaxis, tritonias, montbretias, etc., etc., flourish in a way that makes one envious.

The little formal flower garden is another of the many interesting enclosed portions that go to make up this "Kew with the roof off." Here are eleven big old specimens of Dracæna indivisa, and underneath them and around them are beds of daffodils carpeted with oxalis. Zonal pelargoniums are left out all the year round, and only removed when a new style of planting is to be adopted. If they grow over high for bedding, all that is necessary is to cut them back from time to time, and when they grow too woody they can be placed in the borders. Lapagerias clothe the lower walls, and Iris fimbriata and I. tingitana flower in borders edged with Lithospermum prostratum.

The Long Walk.

That the gardens are terraced has already been suggested. The walks are mostly at right angles to each other, and so one obtains striking views along these, and almost every one shows distinctive vegetation. The Long Walk is a place to linger long in, for on either side are the choicest trees and shrubs, with here and there a common one, planted apparently to enable the visitor to recognise at least some of the subjects. So many Cape, Australian, and New Zealand plants alter so much in general appearance when growing freely as at Trescoe, as compared with the pot-grown plants one has become more or less familiar with, that the Long Walk is a long series of surprises. The giant Eucalyptus globulus, 45ft. high, are readily recognisable, and Araucaria excelsa, 35ft. high, is as symmetrical as any small plant seen in Covent Garden; but Psoralea pinnata, 16ft. high, and in bloom, assumes a new aspect. Eurya latifolia has flowered out of doors here. Fuchsia cordata, Bucklandia populnea, with its big red stipules; Tetranthera californica, Clethra arborea, 20ft. high; Acacia longifolia, great bushes full of flower; Pittosporum Colensoi or tenuifolium, as fragrant as a huge flask of Eau de Cologne; Entelia arborescens; fine examples of the popular palm Trachycarpus excelsa; Griselinia lucida, a big plant; and the old favourite Sparmannia africana, are just a few of the inhabitants of this walk. Buddleia globosa and B. variabilis, Senecio grandifolius, and grand old hydrangeas are also to be found here among a host of plants drawn from many lands, and that keep in perfect health in this wonderful climate and under the care of Mr. Dorrien Smith and Mr. Jenkin.

The Dracæna Avenue.

It is quite impossible to do justice to Tresco Gardens in the space at command, or give an adequate idea of its extent and arrangement. For practically all Himalayan, Cape, and New Zealand plants it is a paradise, and to many Mexican, Californian, Mediterranean, Chinese, and Japanese subjects that need greenhouse culture in most parts of the country the gardens offer a comfortable home.

The dracænas, D. indivisa and D. Draco, are one of the features of the gardens, and one walk passes under an avenue of much branched specimens. The ground beneath is covered with hydrangeas, pegged down, and these in their season flower grandly and produce a mass of bloom.

The Glass Department.

There are glass-houses at Tresco, but these are chiefly devoted to the culture of choice fruits such as peaches, grapes, and nectarines, and to tomatoes. Everything is well-cared for, and would attract considerable attention in a garden where the outdoor occupants were of less interest. Freesias are grown in quantity, in beds out of doors, and in frames; others are in boxes and pots, but all of them are regarded as hardy plants to be dealt with after the fashion of daffodils. The secret of success is fresh air, and a thorough drying off after flowering.

It is an easy matter to keep salads and choice vegetables supplied in quantity the year round at Trescoe, with the aid of frames and the fine sunlight that seems never to fail, or at any rate, is never obscured by a fog. The needs of the kitchen and table are by no means forgotten at Tresco, and in this department Mr. Jenkin is as much at home as in the Long Walk.

The Giant Puya.

I think it was at one of the Old Drill Hall Shows that a huge spike of Puya chilensis was exhibited from the Tresco Abbey Gardens, and created no small stir by reason of its size and the beauty of its peacock-blue flowers. The spike came from a huge mass of this bold plant growing in a sheltered corner, a corner many yards across, which it has taken complete possession of. It is really only one plant, but as the stems have bent downward and outward they have been layered, and so a magnificent specimen has been produced. It first flowered at Tresco about forty-six years ago, and now, as then, it is one of the show plants in a garden that overwhelms one with its variety and its surpassing interest.

Charles H. Curtis.

*** A second article on the horticultural features of the Scilly Isles will be published in our next issue (January 11). This will be devoted to the great flower-growing industry, and will be fully illustrated.

TRESCO ABBEY: OLD ABBEY RUINS AND DRACÆNA INDIVISA VERA.

WALL FERNS.

Ferns may be roughly classed under two categories, those which grow in the chinks of rocks, and those which grow in more or less deep soil. Among the former class naturally we find a number which are adapted to inhabit the chinks and crevices of old walls, filling the interstices of the brickwork or masonry, or revelling in the deposits of leaf-mould and of past generations of themselves, which have found a lodgment in their angles, and recesses, or accumulated on their tops.

Their presence in such situations is, of course, largely determined by the climate, the amount of rainfall, and the absorptive nature of the wall materials, since it is evident that, elevated as they are from the soil proper, and exposed, as they must be to drying winds, a long-continued period of drought would involve great risk of their entire extermination. Nature, however, has gifted many of these rock and wall-loving ferns with a really remarkable power of survival under such trying conditions as would simply bake and dessicate the greater number of the fern tribe if similarly exposed.

The little Ceterach (C. officinarum), for instance, may be noted in periods of drought to present the most forlorn and shrivelled appearance possible, its little green fronds being curled up, and only their rusty brown backs visible. So it may remain for weeks, and if we pull one out of the wall it will come away with some of the mortar, literally as dry as a bone. Plunge it, however, into a pail of water, give it a thorough soaking, and, lo! the little fronds swell and flatten out, the rusty scales modestly retire into the background, and in a few hours the plant is entirely resuscitated, a process which, of course, in Nature, is effected by the first thorough drenching with rain.

TRESCO ABBEY: VIEW DOWN THE LONG WALK.

So great, indeed, is the resistant faculty of the Ceterach in this direction that I once found a plant or two of C. officinarum crenatum in Asia Minor, put them into an envelope, and into a breast pocket, where they were only discovered some months later, after my return, and yet, treated as above suggested, overnight, they were ready to pot up next morning, and resumed growth as if nothing had happened.

The common Polypody (P. vulgare), a wall, roof, and tree bark tenant, can also withstand drought for long periods, but this has a stout fleshy rootstock to help it, which the Ceterach and other "resurrection" ferns, as they may be termed, do not possess as a stand-by. Among native wall ferns the common Hartstongue figures prominently in many places, and is peculiar in the fact that it is the only one of the wall persuasion which is equally at home in such positions and in the soil proper. Naturally, it can never attain its full size unless it has ample soil accommodation, but none the less does it make pretty and thoroughly healthy plants, under conditions where it has absolutely nothing but old mortar to root in, and not much of that.

The various native Spleenworts (Aspleniums) are all wall lovers, and in their case such a situation constitutes a measure of protection for them, since their comparatively small size would render their survival impossible in soil conditions in which the soil-loving species, like Lastreas, Lady ferns, and Shield ferns assume comparatively gigantic dimensions. The Bladder ferns and the Oak and Beech ferns also affect rocks and walls, though not averse to forming dense colonies on shallow deposits of leafy soil and their own debris, where they are protected by rocky conditions beneath from invasion by the larger species named.

In damp climates, such as we get in Devon and elsewhere, we may find the stone dykes, formed of rough layers of stone facing, and backing of solid earthen mounds, to be full of seedlings of many species lining the chinks and crevices, since these naturally form capital nurseries for the youngsters, independent of their subsequent aspirations, but, as might be expected, it is the wall ferns proper which here "gae to the wall" in a different sense, the robuster ones crowding them out by virtue of the ample supply of soil within the dyke, in lieu of a restricted one. Obviously as regards the culture of wall ferns, a chief essential of success is thorough drainage, and equally obvious is it that when planting them, whether in Wardian case or rockery, or merely in pot or pan, the wall conditions should be, as nearly as possible, imitated, and chinks provided in which the ferns can nestle as if at home. The soil should be loose and rubbly, but they should be planted firmly, and watered until they start growth, as, however drought-resisting they may be, they only resuscitate by virtue of their roots being active, and kept so by moist conditions until established. The species we have in view are, first of all, the several spleenworts, the little maidenhair spleenworts, Asplenium trichomanes, of which there are several prettily crested and plumose varieties, Asplenium t. cristata, ramo-cristata, and incisum; the Black Maidenhair Spleenwort (A. adiantum nigrum), a fern on quite different lines, and larger, of which there is a heavily tasselled form, grandiceps; the lanceolate Spleenwort, and Sea Spleenwort (A. lanceolatum and marinum).

The bladder ferns we do not recommend, their fronds are too apt to go brown quite early in the season. The oak and beech ferns form pretty masses, but require loose leafy mould and room to spread; they are not at home in mere chinks, nor is the common polypody. These last three, indeed, do best in shallow pans in peaty sandy soil, and of the beautiful varieties of the last-named, P. v. cambricum and a dozen and more others, grand specimens can be made, and of such a size as rather to take them out of our proper wall fern category altogether.

Chas. T. Druery, V.M.H., F.L.S.

LABURNUM CARAMANICUM.

This is a rather rare type of legume from Asia Minor that for a long time was known as Podocytisus caramanicus, and which is now finding its way into private collections on the slow but sure principle. It is an attractive shrub that never appears likely to make a tree, the height of the tallest specimen I have seen was six feet, and the girth of the entire plant was 10 feet. The habit is that of a spartium, or Cytisus scoparius, but more diffuse, the branches being very slender, densely twiggy, and the top of the main stems is a thicket of growths. It flowers freely during the summer months, bearing small but pretty erect spikes of yellow flowers that recall Coronilla glauca in shape and size.

In common with most leguminous shrubs it has a tendency to get thin at the base, and on this account is not to be recommended for specimen grouping, but planted in thickets in broad shrubberies, grouped freely in the larger types of rock gardens, and where garden and park meet, it is very attractive. Quite young plants should be chosen for the plantation; they will not bloom freely till the second year, but will literally cover themselves with flowers afterwards.

G. B. Mallett.

CULINARY PEAS.

Culinary peas are highly esteemed from the time the earliest crops can be secured until the latest are over. The means for producing very early crops under glass are within the reach of the few only, and obviously on this account the practice cannot be generally followed, and for this reason it will not be now dealt with, but the method of raising early batches for transplanting in the open is more commonly available.

Sowing Under Glass.

There was a time when the early peas were invariably sown in November in the open, but they often suffered severely from bad weather, vermin, birds, and slugs, and consequently were uncertain. This practice is now comparatively seldom followed, nor is it necessary since early varieties of peas have been so greatly improved. Those who have the accommodation of suitable pits, or early peach houses, etc., in which to raise early crops, need not trouble about the old practice.

TRESCO ABBEY: THE DRACÆNA AVENUE.

For these early crops under glass the seeds may be sown in January, thinly, in four-inch pots, and placed in gentle heat, keeping the seedlings in a light position near the glass until they are an inch or so in height, when they should be placed in a cool pit, and be hardened before being planted in the open. A mild day, when the soil is in a suitable condition, should be taken advantage of for this operation, and a carefully prepared and sheltered south or west border, if available, should be made use of. Trenches of convenient depth and width should be cut out, at the same distance apart as the height of the variety to be planted. Carefully turn the plants from their pots, place them in position, and make the soil firm about them. Should the soil be in any way unsuitable make use of some moderately fine and dry material that has been prepared for the purpose. Complete the operation by protecting the rows of plants with sprays of laurel, spruce, etc. When the earliest crops are sown in the open, sheltered borders similar to those recommended for crops that have been raised under glass should be found for them.

Preparing for Main Crops.

Plots may be suitably prepared for main and late crops by being trenched and heavily manured during the autumn or early winter months. Farmyard or stable manures when employed in this manner for peas are best when only in a partially decomposed state, more especially if the soil is of a heavy description. It has been said that manures of this kind are of little or no nourishing value to peas; be this as it may, our crops have little or no other manurial aid than that derived from material of this kind, and their quality invariably leaves nothing to be desired. When preparing for seed sowing land treated in this way should have several inches of its surface well broken over when it is in a tolerably dry state. The drills should be taken out to the depth of from three inches to four inches, and eight inches in width, and for peas of from five feet to six feet in height they should be at least six feet asunder, those for dwarf-growing varieties being correspondingly closer together.

Some advantages may be gained by placing the rows further apart than the distances recommended, the intervening spaces being planted with dwarf crops, such as cauliflower or turnips, but this mode of management is not in all cases convenient.

Sowing in the Open.

Errors are still made, notwithstanding all that has been written about it, by sowing the seeds much too thickly; much harm both from the haulm becoming crowded and because the roots starve each other. In sowing, therefore, pains should be taken to avoid overcrowding.

It is a good plan, particularly in cases where the soil is light and porous, to sow the crops that furnish the midseason and late supplies in trenches. By adopting this practice the roots of the plants are preserved in a cooler and more moist medium than they would otherwise be. They can also be more conveniently supplied with water and liquid manure should assistance of this description be necessary, but whether assistance, in the form of liquid manures, are or are not needed depends greatly upon the tilth of the land. Where there has been an inadequate supply of manure applied much may be done to rectify the defects by a discriminate use being made of these liquids.

Mulching.

The necessity for mulching is another matter that depends greatly upon circumstances. On heavy, deeply cultivated, and well manured land benefit is seldom reaped from it, provided the surface of the soil is frequently and properly stirred. It is only in very dry seasons that mulching works good under these conditions, while in wet ones it does mischief. Difficulties about its employment, therefore, thus sometimes arise, at least, with some of us who are not good weather prophets. In the case of dry, porous, or shallow soils it is different, and upon them mulchings of short manurial litter is more often beneficial.

Successional Varieties.

As a rule, a good supply of peas, from crops sown outdoors. can be maintained throughout the season by fortnightly sowings made from January to July. It will be understood that to accomplish this entails the selection of suitable varieties, but it is not necessary, or really desirable, that a great number of varieties be used. A better practice is to sow sufficient successional crops of a comparatively few approved ones. Tall growers give the longest supply of pods, and the pods should be regularly gathered as the peas become fit for use, because if left later they not only become unfit for the table but also work much injury to the remainder of the crop by distressing the plants.

We maintained an excellent supply of peas last season without an interruption until the second week in November, from successional sowings of the following tall kinds, viz., William the First, Gradus, Thomas Laxton, Veitch's Prestige, Main Crop, The Gladstone, and Autocrat. The earliest crops of William the First and Gradus were sown under glass, and subsequently planted out. Owing to the cold nature of our soil and our low situation we sow a hardy variety, viz., William the First, for the first crop, though it may not always be necessary to use it in the dining-room.

T. COOMBER.

The Hendre Gardens.

THE ELDER-LEAVED VALERIAN.

The true valerians are practically unknown to English gardens, the most probable reason (in respect of the majority) being a lack of every good feature that should welcome them there. From that which is undoubtedly bad, one or two species stand out as superlatively good, and one of these—Valeriana sambucifolia—can surpass many hundreds of border plants valued to-day. This species is a vigorous hardy perennial five feet high, whose leaves are elegantly lobed as its name implies, and whose flowers, in light airy masses of pink and white, maintain a display of three months' duration. Viewed from a distance the plant recalls the white galega, the sheaf-like habit and all-white "cap" of flowers being identical; closer inspection reveals a shade of pink, and the foamy, clustered flowers, minute individually, but a source of admiration collectively, are of an entirely different type.

There is room for such plants as this in the best stocked garden in the land, particularly is this the case where the soil is poor. One can grow the elder-leaved valerian in the poorest of poor soils, and get a good return in flowers that would be difficult with other plants. Cuttings of the young shoots root readily in spring, and pieces of the root will grow if there is a bud or two left intact.

G. B. MALLETT.

Sowing Scabious Seeds.—The sweet scabious is often far from a success in the flower garden, autumn finding the plants at the zenith of their flowering season. To have a good early display of bloom there is no plan to beat that of sowing seeds in heat now, or, at least, before the end of January. A high temperature is not wanted, something about 50 degrees to 55 degrees, and when the seedlings are up they may have even less heat. What the plants want is a long growing season, and when they have this they are generally thoroughly satisfactory.—E. J. K.

THE EUCOMISES.

The great natural order of the Liliaceæ is one of the most prolific in genera, species, and varieties of all bulbous or tuberous plants, and as we think of the various flowers which are broadly grouped among those it includes, we are struck with surprise at the differences which exist within the order. There are few, who, looking at the spikes of the eucomises, would imagine these to be classed with the Liliaceæ, for, assuredly, they are far removed in appearance from the true lilies, which are so queenly in their beauty. But, as we look more closely at them, we realise that there are others in the order still further removed than they, and we see in their structure the affinity which exists. But this note is not intended to be one on the botany of the eucomis, and is designed mainly to advance the claims of the genus to a still greater recognition at the hands of the grower of flowers who cares for other things besides gay colouring and great masses of bloom with little individual character.

I can hardly imagine that there is anyone with sufficient temerity to venture to urge the claims of the eucomis to the suffrages of the gardener because of its colour, for the blooms are not even pure white, and the fascination of the plant lies rather in its singular appearance, its habit, and in its wax-like blooms, although they can only be said to be "whitish." Yet one has seen them employed with striking results in stands of hardy flowers at shows, and some northern exhibitors in particular have been frequently complimented upon their fine spikes of the eucomis. Yet their presence in prize stands of hardy flowers has not passed unchallenged; for it is true that these flowers are not among our truly hardy plants, and that their reputation for hardiness is far from being above reproach. It is whispered, moreover. that some of these exhibited spikes are not from the open, but that they owe their quality to the shelter of the frame or the greenhouse. This may be, so far as regards these individual spikes, but the writer knows of even Scottish gardens where Eucomis punctata has survived and flowered regularly for many years in the open without any protection, although, it is well to say, these gardens were not in the colder parts but in more favoured regions.

Although this is the case, the would-be cultivator of eucomises will be prudent should he not place too much reliance upon their hardiness, but will best show his wisdom by covering the place his plants occupy with some ashes or dry litter in winter, especially for the first winter after planting, as that is the time of trial in ordinary seasons. They ought always to have a sandy soil, made rather rich, however, by adding some good old manure. Choose a sheltered position and plant,either in autumn or in spring, at a depth of five inches.

There are a few species only offered by the trade, and of these one of the best known is E. punctata, which affords us a tuft of long, very ornamental leaves, prettily spotted. From the centre of these rise stout spikes of flowers a foot or more in height, the succulent-looking stems being spotted, and the spikes of bloom of considerable length, and surmounted by a little tuft of small leaves. The flowers are of a dull white, and spotted with rose.

Another good species is E. regia, a handsome one, and if well grown, finer than its sister flower, in some respects, although its blooms are not so white and have a tinge of green about them. We rarely meet in gardens with any besides these two, but E. undulatifolia is not to be despised, as its long leaves are prettily waved along the margins. Another, called E. amaryllidifolia, is said to have greenish flowers, like the last-named, but it has not come under my observation in any garden I have seen.

One more point about the eucomises may be mentioned, and that is the sweet, honey-like odour they possess, which attracts a multitude of small flies or gnats in summer when they are in bloom. Bees do not appear to be attracted by it in the least.

These eucomises are propagated by division, and, while autumn is recommended by some for the operation, one questions its expediency at that season. Spring is more suitable, as the young plants have a chance of becoming well established ere the coming winter.

S. ARNOTT.

SEEDING OF ROOT CROPS.

The past season, though unfavourable to many garden crops, has not, on the whole, been especially so to vegetables, a fact that has of late been amply demonstrated in the excellent produce staged at exhibitions.

On the other hand, it is seldom that such waste of material from seeding, or as it is generally termed, "bolting," occurred as has been the case this year. Late sown and normally grown crops suffered but little, but those raised early, in heat, and planted out in May, with the object in view of having fine produce from July onwards, were, in many cases, complete failures, owing to premature seeding. Leeks and celery, the latter especially, are, when early sown, always regarded as somewhat risky crops, because of their tendency to "bolt," and this is often ascribed to want of water at the roots at some period of growth. This, however, can scarcely have been the cause this year, as at no period in early summer was the soil sufficiently dry to produce any injurious effects upon the most moisture-loving forms of vegetation.

Though referring principally to root crops, some others, as parsley, raised in warmth and planted out in due course, displayed a similar disposition to run to seed rather than produce normal growth. This crop, though of less consequence than the others mentioned, is, nevertheless, one of much importance in northern gardens, while the ease with which it is cultivated makes it very popular with all classes. Apropos to this may be mentioned the unwonted spectacle that for some months past has been witnessed in many parts of Scotland, of whole fields of turnips and mangolds having run to seed, the tall, gaunt, and now almost bare stems presenting a very strange appearance, and, of course, it represents a very serious loss to the grower. In many instances the plants started this abnormal growth direct from the seedling stage, hence no bulb worthy of mention was formed, while in others it set in at a rather later stage, and although bulbs are in evidence, they are of little value. In the south-western districts of Scotland the evil, though present, is not so bad; but throughout the Lothians and still more inland districts, as viewed from the road or railway, the impression might easily be formed that every plant had thus departed from its proper course. The reason assigned for this unusual state of matters by agriculturists is the very sudden spell of hot weather which occurred in July, succeeding a cold ungenial spring, and the equally sudden relapse that followed the heat wave.

JAMES DAY

Galloway House, Garlieston.

ROOM AND WINDOW PLANTS IN WINTER.

With a practically unlimited supply of plants in stove and greenhouse to draw upon, the problem of keeping rooms and windows attractively furnished with flowering and foliage plants becomes a comparatively easy one; but when the plants used in the adornment of the room have to be grown in the room itself things are much more complicated. Then it is not a case of taking away a plant directly it becomes unsightly and bringing in another to take its place; instead of this, we must either make the most of what we have or buy more. As window and room gardeners are not, as a rule, in a position to be constantly buying more, it follows that they must make the most of what they have, and it is to help them in doing so that these lines are penned.

Atmospheric Moisture.

First it may be well to emphasise the need of buying suitable plants, as there are very many beautiful subjects, both flowering and foliage, which are quite unsuitable for growing in an ordinary room, be that room never so warm or never so light. Heat and light, though highly important, are not all that a plant requires; humidity in the atmosphere is almost, if not quite, as essential, and this humidity a plant in a room rarely or never obtains. More especially is this the case in winter, when fires are kept constantly burning, as these dry up what little humidity there may be in the air, besides ofttimes distributing leaf-choking smoke and dust. If owners of room plants were to consult the wishes of their protégés, they would keep a kettle of water boiling when a fire was burning.

Dusty Foliage.

Next in importance to humidity in the atmosphere, I would place freedom of the foliage from dust. It should always be remembered that the entire surface of a leaf is covered with minute mouths, stomata, through which the plant breathes; the leaves are, in effect, the lungs of the plant, and to keep a plant in good health we must see that its lungs are not blocked. To this end all large-leaved plants should be sponged once a week in winter, at least, when a fire is kept going in the room. There is nothing better for this purpose than a little tepid water, brought to the colour of milk by lathering a little soft soap in it. Plants with finely cut foliage, or any which for various reasons cannot be sponged, should be cleaned by syringing them with warm water. It is not, however, advisable to syringe plants that are in flower, as wetting spoils the blossoms; in such a case much, if not all, of the dust may generally be removed by blowing the leaves vigorously with a dry syringe. Where a syringe is not numbered among the possessions and a bicycle is, use the bicycle pump.

Watering.

But paramount above all in the care of room plants is watering; it is not too much to say that plants are either made or ruined by the manner in which watering is carried out. Folk cannot get over the idea that plants require a certain quantity of water at a certain time, and at regular periods. Nothing could well be further from the truth. Once the fact is grasped that a plant should only have water when it needs it, progress will have been made in the art of plant growing. Even in a warm room very few plants require watering more often than twice or thrice a week in winter, while in a cold room the majority will go a week or a fortnight in winter without water, and derive benefit rather than harm by so doing. If any doubt whatever is felt as to whether a plant wants water, give it the benefit of the doubt, and withhold the water. Warm water, or that which is quite hot, is better than cold water in winter; it suits the plants better, and less of it is required.

Draughts and Stagnant Water.

Another important point is to not leave water in the bottoms of vases or other receptacles which hold the plants; not only are very offensive smells engendered by this practice, but the lower roots of the plants are liable to rot off through standing constantly in the stagnant water. All receptacles should be emptied periodically, and if at the same time the surface soil in the pots is lightly stirred up with a pointed stick, much will have been done to ensure that thorough aeration of the soil without which plants cannot for long thrive. As a final word of advice, I would warn readers of the danger of exposing plants to cold draughts. E. J. Kingshome.

SOME BIG CHRYSANTHEMUMS IN PARIS.

Although I have known Paris for over thirty-three years it was not till 1896 that I paid my first visit to a chrysanthemum show there. Like most English chrysanthemum growers I had long entertained the idea that we were far ahead of the French in the matter of big bloom culture for show. I was not disappointed. But since the year 1900, when the National Chrysanthemum Society took over a fine lot of blooms to exhibit there, and when Mr. W. Wells also staged a remarkable collection, a very marked improvement has taken place.

It must not be forgotten that French taste decrees that the general artistic aspect of a show is of far more importance than the enormous size of a few individual flowers, and that what we usually put first the French put last. There is, however, notwithstanding this, a good number of capable big bloom growers, and the flowers that some of them stage would compete very severely with many of those put up by our big growers. M. Calvat, the Marquis de Pins, M. Dubuisson-Foubert (little more than twenty-two years of age), M. Charvet, M. Paul l'Abbe, M. Pecquenard, and one or two others would astonish some of our growers if they could be induced to come over and bring some of their best flowers to our exhibitions.

In going round the Paris show one afternoon for the special purpose of noting the names of a few of the finest blooms, I took note of the following as being worthy of high commendation: F. S. Vallis in large numbers. Mme. Paolo Radaelli, mostly good, one bloom being awarded the second prize in the class for the biggest bloom in the show, the first prize going to the one previously named. W. R. Church was shown in enormous flowers, and was uniformly fine. General Hutton was as big as anyone could wish. Pres. Viger, Mermaid, Marquis Visconti - Venosta, all monsters. Le Bouvier and Chrysanthemiste Montigny, two varieties not so well known here as in France, also belong to the big brigade. J. H. Silsbury, Sapho, Mme. René, Oberthur, Australia, Mr. T. Carrington, Miss Alice Byron, Mrs. T. W. Pockett, Lieut.-Colonel Ducroiset, Souvenir du Bailleul were all flowers that would have required a good deal of beating at any of our leading shows in England. C. Harman Payne.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

INTRODUCTORY.—In the writing of orchid calenders I always feel it my duty to impress upon my readers the fact that there are so many differences in positions, conditions of local surroundings, and also in the facilities provided for the cultivation of orchids, that however expert the writer may be, the advice given cannot possibly be applied to all cases. Therefore, those in charge of plants must use their own discretion in adopting any fresh methods, and I would especially warn them against a material departure from any methods of culture which have been found successful. Should some other method be advocated, I would advise cultivators to try a few of the plants first, and, if found successful, the remaining plants may, in due course, be brought under the new treatment if considered desirable.

PREPARATORY WORK.—With the turn of the days the work in the orchid houses will increase with great rapidity, and preparations should be made at the present time to facilitate the various operations being carried out without delay. While the weather remains open a supply of sphagnum moss should be obtained, for it often happens that there is a prevalence of frost when repotting is commenced, and, it being then impossible to obtain supplies, work is delayed unless the needful supplies have been obtained beforehand. The moss should be carefully picked, washed, and put ready for use. If stored in a cool, damp place, and turned over once or twice a week, it keeps in good condition for a long time. Peat should also now be pulled and made ready for use. We usually have sufficient pulled at this season to last through the potting season. The bracken roots should be preserved, for there is nothing more useful for drainage purposes for practically all kinds of orchids. Care should be observed to have these roots properly dried. If there is the least particle of green woody or sappy substance remaining in them when used for drainage, fungoid growth appears, according to my experience, on them, and this quickly spreads to the potting compost, often leading to undesirable results. The use of leaves as a constituent of orchid composts has been general in orchid collections during the past four or five years, with varying results. Some, who have had the longest experiences with it, have demonstrated its desirability by the results obtained. Others experience have been exactly the reverse. As one who has used leaves with success I must include them under composts to be prepared at the present season. If leaves have not already been gathered they may be easily secured, where they have been blown together in heaps. Dry oak or beech leaves are the best. These, when secured, should be placed in a bag and dipped into a copper or boiler of boiling water; this will destroy all insect life and fungoid growth. The leaves should then be carefully dried again and chopped ready for use. Loam, which is desirable for many of the terrestrial species of the orchid genus, should also be selected and made ready; good fibrous turfy loam, with the fine soil removed, is the best for the purpose. This should be stored in a place where it may become warmed and ready for use when required.—H. J. Chapman, Oakwood, Wylam-on-Tyne.

STOVE PLANTS.

TEMPERATURES.—We usually endeavour to have a season of rest in the stove by reducing the temperature during the shortest days of the winter, or in other words from about the middle of November till early in February. During this period we maintain, when the frosts are severe, a night temperature of 65 deg, with an advance in daytime of 5 to 10 deg. Careful attention must be paid to syringing, which ought to be done only in dry bright weather and during the forenoon. As much artificial heat is required to maintain the temperatures, the damping of paths and borders must be done when necessary for preventing an excessive dryness of the atmosphere.

COMPOST FOR POTTING.—A supply of good fibrous loam and peat is essential for stove plants. Because of the liberal waterings they require throughout their growing season, their potting compost must be of the best possible quality to ensure its remaining sweet and the roots continuing in a healthy condition. A supply of charcoal, lime rubble, silver sand (coarse), and broken oyster shells will also be required for incorporating with the soil.

BEGONIA GLOIRE DE LORRAINE.—Stock plants of Gloire de Lorraine as they have done flowering should have the old flower stalks removed, and the stems cut down to within nine or twelve inches of the surface, and placed in an intermediate stove near the glass to start them into growth and thus ensure an early supply of cuttings.

POINSETTIAS. — As these are removed from their flowering quarters place them in a dry position to ripen the wood preparatory to resting. A temperature of about 50 deg. is sufficient. They must, however, be carefully examined at intervals of a few days, and be watered when necessary to prevent excessive dryness, and on no account allow the shrivelling of the bark to take place.

GLOXINIAS.—If an early display of flowers of these beautiful flowering plants is wished for select tubers that ripened earliest, and place on a shelf near the glass where light is abundant, in a temperature of from 50 to 55 deg. In the case of the earliest batch we succeed best by allowing the tubers to remain in the pots in which they were grown last year, and give them a top dressing of rough fibrous peat, loam, and cow manure (dried) in equal parts. This is given when the plants are making new growth. As the flower buds appear a further assistance is given, bonemeal or liquid manure being used.

WATERING.—Careful attention must be given to watering, for stove plants are at this season liable to injury when applied in excess. When the soil has been moderately dry, sufficient water should be given to well moisten the whole of the ball. It is essential to use water not colder than the temperature of the structure in which the plants are growing.—JOHN DONOGHUE, Bardon Hill Gardens, Leeds.

FRUITS UNDER GLASS.

STRAWBERRIES.—The earliest batch will most probably have been put in the early vinery that was started the first week in December. Those selected should have had the most prominent crowns, and been the best-rooted plants. If any small side growths appear these should be removed to throw the strength into the centre crown. These being the first to give fruit early they should have the best of attention in the way of watering and keeping them close to the glass. For early fruiting they are best started in a bed of fresh oak or beech leaves (to secure strong root action), and given a medium top temperature, increasing this as the trusses appear so as to elongate the flowering shoots somewhat. This is important, as the trusses can then be staked and the fruits kept from damage by watering. When they reach this stage they are best placed on a shelf in a house where there is a temperature of 60 to 65 deg., where they can get a little air when the weather is favourable. Weak liquid manure may also be given to help them throw out the flower stems. If a good succession is required put another batch in a month later. If the soil has been washed away from the crowns a little top-dressing may be given. It is as well to dip the plants in some insecticide if they have to stay in the vinery, on account of red-spider and other insects.

CUCUMBERS.—A sowing of these should be made singly, or two seeds be put in a clean, small 60-sized pot; place in a brisk heat in a box of leaves covered over with some glass, till the seeds germinate. At this time of the year it is as well to sow a few extra seeds to ensure enough plants. As soon as they are in rough leaf put the seedlings on a shelf near the glass in a brisk temperature, but away from draughts. Shift them on into 54-sized pots as they become rooted, remembering that a small shift is preferable at this time of the year, because the soil remains saturated if there is little root action, and this will bring on mildew. Telegraph is still one of the best varieties to grow, especially for early fruiting.

FRUIT-ROOM.—Grapes will have been cut and bottled; white bottles are preferable to black ones, as they allow one to see whether the portion of stem cut with the bunch is in water or not. If charcoal is placed in the bottle there is no need to change the water. Care should be taken not to make any dust in the room, as this may adhere to the skin of the grape, and cannot be blown off, especially if the room is at all damp. A temperature of 45 degrees is sufficient. Examine the bunches occasionally, and remove all decayed berries.

POT VINES.—Those that were started in November will be showing bunches, and the temperature should not be allowed to fluctuate much; 65 to 70 degrees at night, and 70 to 75 degrees by day affords sufficient heat. The vines will be plunged in a bed of leaves, and probably with pipes under this, and until the roots are well in action 65 to 70 degrees is ample bottom heat. A thermometer should be placed in the leaves. The selection of bunches should be deferred as long as possible; select the best and as evenly as possible up the rod. Do not hurry to tie down the shoots, as this stops the flow of sap, and crooked shoots and poor bunches may result. Stopping should also be left till the shoots have two or three leaves, so as to draw the sap up into the bunches. Air should be given on all favourable occasions, if only for a short time, to sweeten the house. When watering thoroughly soak the soil. If there is not much room for water place a piece of zinc round the pots about six inches wide; this will allow for plenty of water, and will also enclose the top-dressing later on.

EARLY VINERY.—This, started the first week in December, will have vines nearly bursting; instead of using much fire heat it is better to close the house a month sooner and apply no fire heat till the buds begin to burst, as the growths come away stronger, more evenly, and better. As soon as the buds burst raise the temperature to 60 degrees at night and 65 to 70 degrees by day. Permanent vines cannot be rushed like pot vines, and must be treated to give returns for a number of years. Excessive fire heat is one of the greatest evils in grape culture. Close the house with as much sun heat as possible, and well syringe the walls and paths. If the border was in good condition when the house was started no water should be given till growth begins, when it should have a sufficient quantity to soak it through. The water should be given out of tanks in the house or else be slightly warmed. The shoots should be well advanced before being tied up. Sometimes vines are most erratic in breaking, through bad planting, cold border, or bad drainage, but no doubt notes were taken the previous year as to their behaviour. If a few strong shoots get ahead the weak ones will fail and a gap in the rod will result.

LATE VINERIES.—All pruning should be finished at the turn of the year, for with lengthening days the vines will want to start. Cut off all old back spurs, and put some styptic over the cut. If the outside borders are well drained and lie warm they do not necessarily require to be covered up in ordinary weather, but the recent heavy rains may have made the borders very wet. If this is so the borders should be covered up with some long stable litter and have old glazed lights placed on the top of this to keep off the rain, but not to exclude sun and air. We have found this protection necessary for the first time in eleven years. Have inside borders top-dressed and cleaned; when taking off the old top soil do not disturb the young roots. Artificial manures should be used sparingly in top-dressing, especially on the young roots; loam mixed with mortar rubble, wood ashes, and bonemeal is good material.

MELONS.—Seeds should be sown as for cucumbers. Hero of Lockinge and Blenheim Orange are excellent varieties for early crop.—A. B. WADDS, Paddockhurst Gardens.

A MILD CHRISTMAS DAY.

Christmas found us with an unusual quantity of bloom and berries in the garden. Pear trees were in bloom, and strawberries are colouring their fruit under a handlight in the kitchen garden, besides carrying a quantity of green fruit the size of walnuts. Double and single anemones, St. Brigid varieties, were in full flower in the herbaceous border, and with a light placed over them will doubtless keep blooming all the winter, being perfectly hardy, and easily raised from seed, they are allowed to flower where they are sown, thinning the seedlings when they are large enough to handle.

Rose Frau Karl Druschki gave some nice blooms, and it is one of the best of autumn roses; Madame Lambard was also in flower. Mignonette, antirrhinums, primroses, polyanthus, and Stenactis speciosa were in flower, and snowdrops could be seen coming up through the grass, and a few were unfolding their white petals; tritomas still look gay amongst the pampas grass, but the wet weather spoilt these in the autumn. Physalis Alkekengi, or winter cherry, was still one mass of colour in the beds, and these are indispensable for winter decoration for mansion and church, keeping fresh for a considerable time. A pretty sight was, and is, the strawberry tree, Arbutus Unedo, the red, round berries hanging amongst the clusters of white blossom; whether it is owing to the wet dull summer, or other atmospheric conditions, this tree has not been seen here to better advantage before; on Christmas Day it was one mass of red and white.

Escallonia macrantha had still some flowers open, and this makes a splendid shrub for the lawn, the foliage always being a healthy dark green. Of climbers, Chimonanthus fragrans, Ceanothus Gloire de Versailles, and Jasminum nudiflorum were very bright. Choisya ternata does well here, but owing to wet sunless weather it has not bloomed in such profusion as it generally does; it is perfectly hardy, and stood 20 degrees of frost last winter without any protection whatever, although it is planted on an elevated exposed position open to the east and west winds. It will thrive in either peat or sandy loam and leaf-mould, and can be easily increased by layering. It has a great objection to being constantly shifted, as the roots are very coarse, therefore, it should be planted in a permanent position. It also makes a good plant for covering walls, and it blooms very freely, the flowers being sweet-scented and the foliage a bright green.

Hydrangeas planted outside in a large bed have just gone out of flower, and most of the varieties are quite hardy, and come here both blue, pink, and white; these are among the most beautiful of summer or autumn flowering plants, and these also stood 2 degrees of frost last season without protection outside. Large plants in tubs are placed in a cool structure in the spring.

In secluded places the furze was to be seen in full bloom; by the way, this makes a splendid hedge, but is frequently cut at the wrong time of the year, and so little blossom is seen on this fine shrub in early spring.

A. B. WADDS.

Paddockhurst Gardens, Sussex.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Ninepence per line, the minimum charge being Five Shillings. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

The last meeting of the old year was held on the last day of the year. There was a small exhibition, and the people who foregathered were more eager to offer good wishes than to do business or take horticulture seriously.

FLORAL COMMITTEE.

Winter-flowering plants were extensively displayed by Messrs. James Veitch and Sons. Chelsea, and the group included Calceolaria Burbidgei, Moschosma riparium, Luculia gratissima, Leonotus Leonurus, Jacobinia chrysostephana, J. coccinea, Coleus thyrsoideus with its blue spikes of bloom, winter-flowering begonias in great beauty and variety, and the pretty and interesting Pavonia kermesina. A group of Dracæna Doucetti with the more yellow-leaved D. Dallieri, was submitted by Messrs. Hugh Low and Co., Bush Hill Park, Enfield; both are good dracænas. This firm had also a batch of Euphorbia jacquiniæflora, a group of cyclamen, Otaheite oranges, and a fine lot of winter-flowering carnations.

The splendid bunches of zonal pelargoniums set up by Messrs. H. Cannell and Sons, Swanley, were a fine show, and the varieties Arabic, King Victor, Kingswood, The Mackintosh, Hibernia, Sir Thomas Hanbury, and Lucania were particularly good in colour, size, and form. Berried plants were a leading feature of the considerable display made by Messrs. Wm. Cutbush and Son, Highgate. In their group they had batches of pernettyas, the various colours being grouped together, with these were Otaheite oranges, ardisias, Hamamelis arborea, Adonis amurensis, Iris alata, I. histrioides, Sternbergia hyemalis, and daphnes. In another group the Highgate firm exhibited a selection of winter-flowering carnations, showing Robert Craig, Aurora, Mrs. S. J. Brooks, Britannia, the fine new Marmion, Mrs. Burnett, The Belle, Harlowarden, Rose Doré, Fiancée, and the scarlet St. Louis.

Sarracenia purpurea, a big clump, lifted from the open ground the previous afternoon, with the pitchers filled with ice, was brought up by Mr. W. A. Cook, from Sir Edmund Loder's garden at Leonardslee, Horsham. This species does well out of doors, unprotected at Horsham. Messrs. Paul and Son, Cheshunt, sent a bunch of flowers of the new perpetual musk rose, named Snowstorm, and also a bunch of flowers of Montanoa bipinnatifida. Messrs. J. Peed and Son, West Norwood, submitted a collection of alpines and succulent plants, with a few lachenalias. Cotoneaster Francheti, a graceful grower with neat leaves and an abundance of bright coral red berries, was well shown by Messrs. James Veitch and Sons, Chelsea.

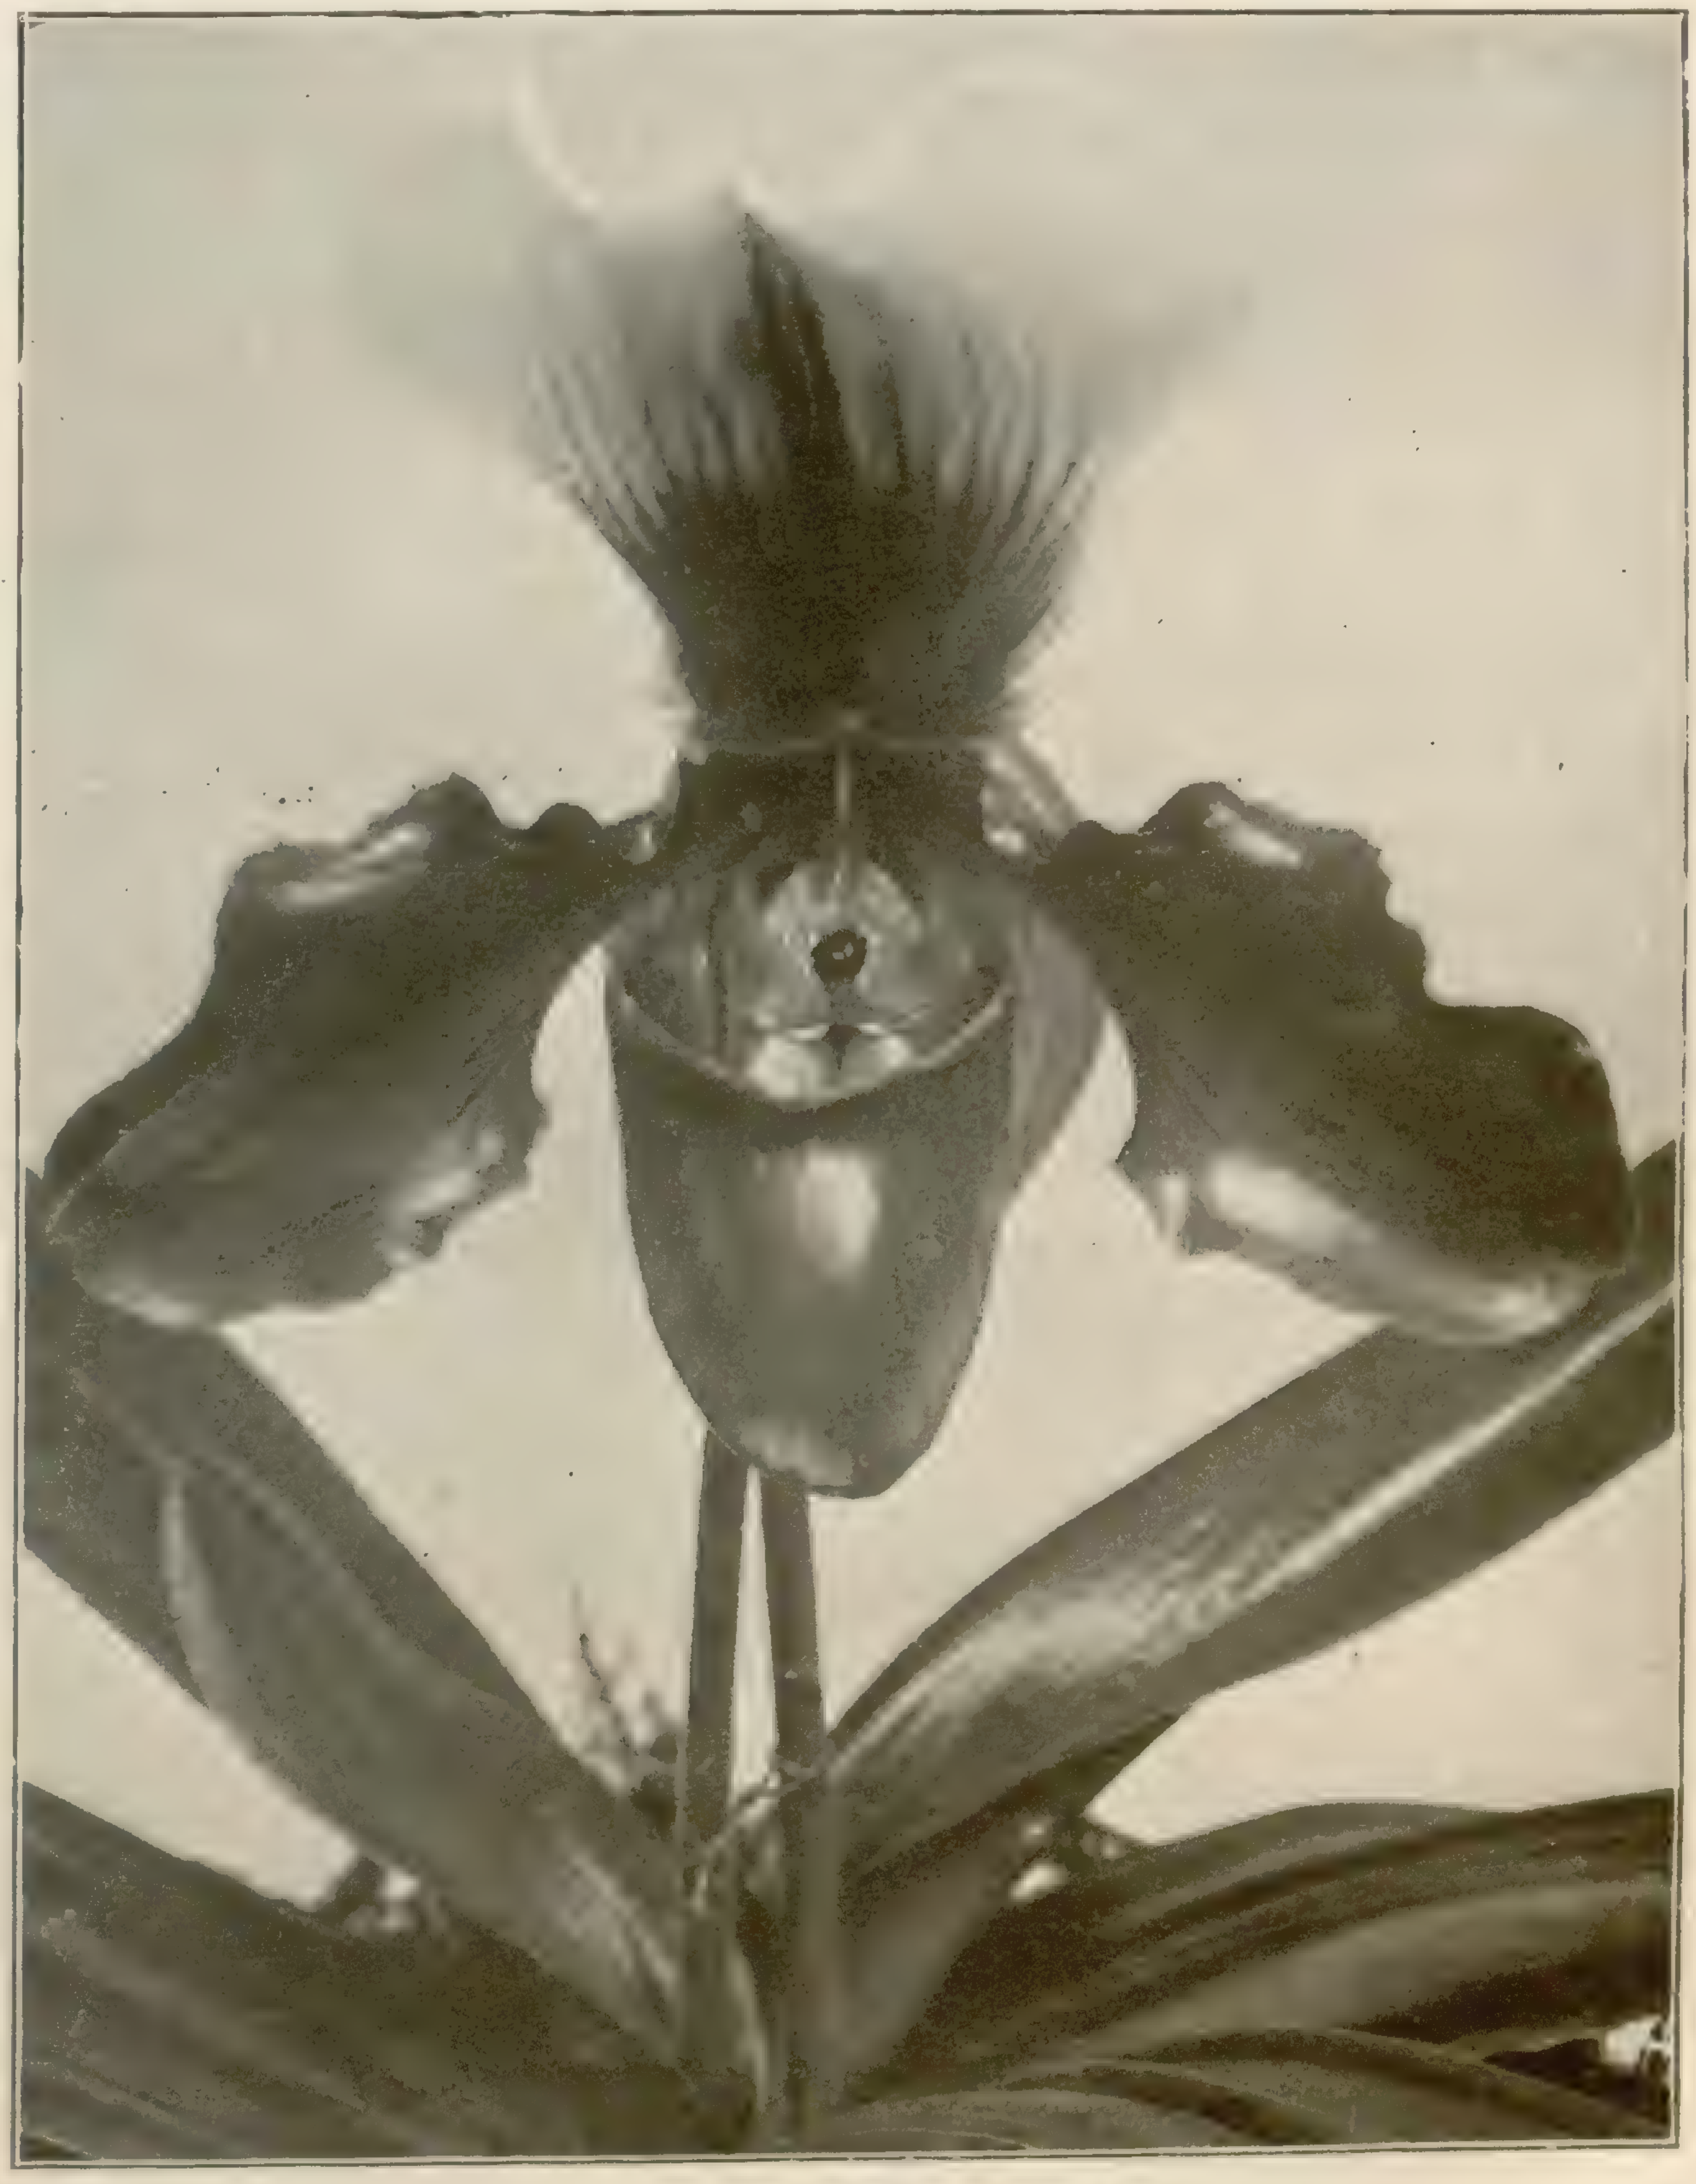
Primula obconica grandiflora Hayes' Place Double, is the far too lengthy name of a very pretty strain of double-flowered P. obconica, and one that should secure a large amount of popularity if distributed; an A.M. was granted. Messrs. H. B. May and Sons, Edmonton, staged a group consisting of batches of Euphorbia jacquiniæflora, scarlet and white-bracted poinsettias, winter-flowering carnations, and Dracæna Her Majesty, the latter of handsome form and rich colouring.

ORCHID COMMITTEE.

Cypripedium insigne Arnoldiæ was shown by Mr. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford. Mr. Alexander, orchid grower to Major Holford, C.I.E., Westonbirt, Gloucester, brought up the fine Cypripedium Moonbeam (F.C.C.), a white and yellow-green cross between C. Thomsoni and C. Sallieri; and C. Bellerophon, with brown sepals and petals and a white, purple, and green dorsal sepal. From the same collection came Lælia anceps Schroderæ, var. Theodora, with three very large bright flowers, each with a vivid crimson-purple lip. Mr. F. Corney, gardener to J. H. Craven, Esq., J.P., Beeches, Keighley, Yorks, submitted Cypripedium Troilus var. Cravenianum (A.M.), a big flower with brownish-green lip and petals, and a very broad green, purple spotted, white banded dorsal sepal; this is derived from C. insigne Harefield Hall, which it greatly resembles, and C. nitens, Ball's var.

Very beautiful was the new Odontioda Craveniana (A.M.), shown by Messrs. Charlesworth and Co., Heaton, Bradford. This had a spike of eight medium-sized flowers of a deep rich scarlet hue, with yellow mottlings on the broad apex of the lip. The parents of this hybrid are Cochlioda Noetzliana and Odontoglossum cordatum. M. Mertens, Ghent, showed several beautiful odontoglossums, but, unfortunately, none were named, and, for the matter of that, there was no card to denote from whom they came.

Some finely-grown cypripediums were shown by Messrs. Hugh Low and Co., Bush Hill Park, Enfield, and among these there were splendid flowers of C. Mrs. W. Mostyn Chardwar var., C. insigne Sanderæ, C. Euryades Charlesworth var., C. Maudiæ, C. Advastus Marie, C. Leopoldianum, and C. Arthurianum pulchellum. Messrs. Moore, Lim., Rawdon, Leeds, showed a small group of cypripediums, that included C. insigne Sanderæ, C. aureum virginale, C. Niobe, etc. Messrs. Cypher and Sons, Cheltenham, showed a charming lot of orchids, displaying fine odontoglossums, Lælia anceps Chamberlainianum, L. autumnalis alba, calanthes, and Cypripedium insigne Sanderæ, Miltonia Bleueana nobilior, Zygopetalum Mackayi, and Oncidium obryzatum.



CYPRIPEDIUM MOONBEAM.

Exhibited by Major Holford, at R.H.S. Meeting, December 31, 1907, and awarded a First Class Certificate. Flowers, large, petals and lip rich yellow-green; dorsal sepal yellow-green at base, white at apex, and marked with purple.

FRUIT COMMITTEE.

A very fine display of apples and pears was well arranged by Messrs. J. Veitch and Sons, Chelsea, who set up their fruits in neat baskets on soft wood wool. It was a splendid exhibit for the season of the year. The pears of special note were Directeur Alphand, Olivier des Serres, Bellisime d'Hiver, Marie Benoist, Easter Beurre, Nouvelle Fulvie, and Bergamotte Esperen. The apples were grandly shown, and a few of the finer of the hundred and forty varieties were King of Tomkins County, Withington Fillbasket, Newton Pippin, Hambling Seedling, Lord Derby, Bowhill Pippin, Langley Nonpareil—a new cross between Peasgood's Nonsuch and Cox's Orange Pippin, and partaking far more of the latter than Charles Ross, which is a similar cross; Langley Favourite—a useful cross between Bismarck and Cornish Gilliflower, Cox's Orange Pippin, The Queen, Lane's Prince Albert, Crown Apple—very bright; Bismarck, very fine; Tyler's Kernel, Bramley's Seedling, beautifully coloured; Blenheim Pippin, Duke of Beaufort—a very late keeper; Colonel Vaughan, Brabant Bellefleur, Christmas Pearmain—beautifully coloured, shapely, and firm; Allington Pippin, Blue Pearmain—a splendidly solid apple; Hormead's Pearmain, Barnack Beauty, a late dessert variety of fine shape and appearance; and a fine dish of Winter Peach.

A collection of twenty-two varieties of pears and the same number of apples was set up by Mr. W. A. Cook, gardener to Sir Edmund Loder, Bart., Leonardslee, Horsham; all the fruits were from orchard trees. The pears were most attractive, and the best dishes were of Beurre Baltet père, Glou Morceau, Beurre Alexandre Lucas, Duchess de Nemours, Le Lectier, Beurre de Naghan, Catillac, and Easter Beurre. A good potato that passed the cooking test satisfactorily was Messrs. Dobbie and Co.'s Favourite; a First Class Certificate was awarded.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Cypripedium Moonbeam, from Mr. Alexander, orchid grower to Major Holford, Westonbirt, Gloucester; to Potato Favourite, from Messrs. Dobbie and Co., Rothesay.

Award of Merit.—To Odontioda Craveniana, from Messrs. Charlesworth and Co., Heaton, Bradford; Cypripedium Troilus Cravenianum, from J. H. Craven, Esq., Keighley; to Primula obconica grandiflora Hayes Place Double, from E. A. Hambro, Esq., Hayes Place, Kent.

MEDALS.

Gold Medal.—To Messrs. James Veitch and Sons, Chelsea, for apples and pears.

Silver-gilt Flora.—To Messrs. James Veitch and Sons, Chelsea, for winter-flowering plants.

Silver-gilt Banksian.—To Messrs. H. Cannell and Sons, Swanley; Messrs. W. Cutbush and Son, Highgate.

Silver Flora.—Messrs. Cypher and Sons, Cheltenham; Messrs. Hugh Low and Co., Bush Hill Park, Enfield; Messrs. H. B. May and Sons, Edmonton.

Silver Banksian.—Messrs. Hugh Low and Co., Enfield (orchids); Messrs. Moore, Lim., Rawdon, Leeds; Messrs. J. Peed and Sons, West Norwood, S.E.; Mr. W. A. Cook, gardener to Sir Edmund Loder, Bart., Leonardslee, Horsham (fruit).

Bronze Flora.—Mr. W. A. Cook, Leonardslee Gardens, Horsham, for Sarracenia purpurea.

Colchester Horticultural Society.

The annual meeting of this society was held at the Town Hall on Monday, December 16, the Deputy Mayor presiding over a goodly number of members.

In the report presented to the meeting the committee congratulated the members on the strong financial position the society has attained owing to the success which attended the exhibitions, and to the careful control of expenditure. There was a balance in hand of £112, and the committee felt they had an adequate reserve fund. It was recommended that the summer show for 1908 be held on Wednesday, July 8, and the autumn show on Thursday, November 12. Owing to the pageant being arranged to be held during the last week in June, 1909, the committee had considered the question of altering the usual show arrangements in that year, and they suggested that it might be advisable to hold a spring show in that year instead of a summer one.

The balance-sheet showed that the receipts for the year, with balance of 1906, were £517 17s. 11d., of which the sum of £175 17s. 6d. was received in the form of subscriptions, £41 1s. special prizes, £166 9s. 5d. gate money at the summer show, £50 17s. at the autumn show. The expenditure included: Prizes, £171 16s. 3d.; printing and stationery, £43 6s. 10d.; advertising, £15 6s.; bands, £32 8s.; hiring account, £40 16s.; judges, £12 10s. 10d.; bill posting, £19 15s. 10d.; stamps, £11 8s. 3d.; secretary, £20; illuminations, £9 17s. 6d. The balance on deposit and in bank is £112 6s.

Mr. Orpen proposed the adoption of report and balance-sheet, and on the motion being put to the meeting it was carried.

The hon. officers: Captain Tufnell, hon. treasurer; Messrs. P. R. Green, assistant hon. treasurer; C. H. T. Marshall and C. E. White, hon. auditors, were re-elected, and thanked for their past services.

On the election of the committee being proceeded with the following were elected members: The Mayor, Major Buckle, and Messrs. E. P. Baker, R. B. Beard, W. Bibby, W. W. Bunting, A. Cant, C. E. Cant, F. Cant, F. Chapman, W. Cheshire, J. Claydon, C. Gall, G. B. Halls, C. H. Martin, C. E. Rice, A. S. B. Sparling, R. W. Wallace, and H. H. Weatherall.

A vote of thanks to the Deputy Mayor for presiding closed the proceedings.

Southampton Royal Horticultural Society.

The annual meeting of this society was held in the Mayor's Parlour at the Audit House, with the Mayor in the chair.

The annual report and statement of accounts was submitted by Mr. Blakeway, who said that, notwithstanding their many difficulties, they had a surplus of £1 7s. 6d. on the year's work. Their subscriptions this year were 6s. better than the highest subscription for the past ten years, and this, although the amount was small, was highly satisfactory.

Mr. Toogood having seconded the motion, the report was unanimously adopted.

The balance-sheet showed that the receipts, including the amount brought forward, were £715 8s. 10d., and the expenditure was £700 17s. 3d., leaving £14 11s. 7d. cash in hand. There was a credit balance of £49 4s. 1d., as against £26 10s. 11d. last year.

ELECTION OF OFFICERS.

After some discussion with reference to the schedule for 1908, during which various recommendations were made to the Council, and Mr. A. Munt kindly offered a cup for competition, the election of officers was proceeded with. The president and vice-presidents of last year were re-elected, and Sir Alfred Wills and Messrs. R. C. W. Dixon, J. R. Anderson, and C. H. Farnham added to the list of vice-presidents. Messrs. Green, Moberly, and Green were reappointed hon. solicitors, Mr. H. J. Blakeway was re-elected chairman of the Council, Mr. A. Doggrell vice-chairman, Mr. A. G. Thompson hon. treasurer, and Mr. C. S. Fuidge secretary. Messrs. G. Busby, N. O. Desborough, G. A. E. Ebborn, Wilson, W. E. Edwards, and J. T. Robb were elected members of Council.

Reading Gardeners' Association.

At a recent fortnightly meeting of the above association, held in the Abbey Hall, Mr. H. J. Jones, the well-known trade grower and exhibitor, of Lewisham, delivered a most practical and exhaustive lecture on chrysanthemums, from the cutting to the drawing-room and exhibition table. For ninety minutes the lecturer kept his audience fully interested, as he treated minutely with details of culture, etc., from the time the cuttings were taken to the show day, when the flowers were staged for the judges' examination. He strongly impressed upon his audience that attention to the very smallest details very often decided whether the first or some other prize was obtained. The first important point touched upon was, naturally, propagation, and under this heading advice was given as to size of cuttings, soil, light, the best method of striking, time, etc. Then followed directions as to the first shift, size of pots, subsequent shifts, constituents of a good compost, date and timing of buds, stopping, housing, temperature, damping, ventilation, selecting and staging for show. There was very little time left for discussion, but a good deal of information was gained by the questions asked by Messrs. Hinton, Durward, Judd, Exler, Wilson, and Goodyer. A very hearty vote of thanks, on the proposition of the chairman, was accorded to Mr. Jones for his very instructive paper.

Mr. G. Hatch, of Cavenham Park Gardens, Mildenhall, Suffolk, sent twelve splendid bulbs of Sutton's Selected Ailsa Craig onions, which had recently been awarded first prize at Bury St. Edmunds show and also first prize at the Norwich Chrysanthemum Show, and Mr. A. F. Bailey, of Leopold House Gardens, Reading, exhibited two seedling plants of Cryptomeria gracilis.

Windsor Rose Society.

At the annual meeting of the Windsor, Eton, and District Rose and Horticultural Society, which was held in the Guildhall Council Chamber, with Mr. W. Fairbank in the chair, a very satisfactory report was presented to the members.

The receipts for the year, with the balance of £5 18s. 3d. from the previous year, amounted to £252 16s. 5d. Of this sum £156 11s. 6d. were subscriptions, and £42 19s. gate money. The expenses were £237 13s. 1d., leaving a balance in hand of £15 3s. 4d. The assets of the society amount to £102 16s. 9d.

Both report and balance-sheet were adopted. In the course of the subsequent business it was decided, on the motion of Mr. Romaine, seconded by Mr. Keppell Gifford, to extend the radius for local classes to within ten miles of Windsor, and include also the whole of Berkshire.

A vote of thanks to the chairman terminated the proceedings.

New Year Gifts.—If you wish to give an acceptable present to a friend whose hobby is his garden, his poultry, greenhouse, rabbits, or any other rural pursuit, you cannot do better than send to the Publishers of the Gardeners' Magazine, 148-149, Aldersgate Street, London, for the new catalogue of books on gardening and live stock. Amongst the many interesting and practical works is the recently published volume, "The Flower Garden," universally commended by the Press, and of which a prospectus may be had for the asking.

The Begonia Mite.—The note on this troublesome insect (p. 787), and the advice that was given to supply plenty of moisture for keeping it in check are sound, and doubtless moisture in abundance materially assists the plants to withstand attacks. Where a stock of plants is badly affected the best remedy I have found is a solution of "Niquas," of the strength recommended for destroying insect life. We were much troubled by mite attacking not only begonias, but also cyclamen, and finding this insecticide so useful generally we tried it, with the best results. Plants attacked with the mite should be dipped in the solution, care being taken when immersing the plants that every part of leaf and stem is thoroughly wetted, turning the plant round several times in the liquid. After immersion the plants should be laid on their sides to drain. With an interval of a day or two another dipping should follow and then once a week or every ten days until the plants are thoroughly cleansed. Fumigating will partly destroy the mite, and hold it in check, but there is no means so effective for destroying insect life as dipping when the size of the plants will permit of it being done.—T. H. Slade, Poltimore Gardens.

THE
GARDENERS'
MAGAZINE

LEADING FEATURES for 1908.

Beautiful and Interesting Gardens will receive prominent attention during 1908, and be freely described and illustrated. Special arrangements have been made to present these in a quite new manner that will be of unrivalled interest. We shall, as opportunites offer, describe and illustrate single gardens as during the past year, but we shall make a special feature of illustrated descriptions of the great gardening districts in the United Kingdom. These will appear at regular intervals throughout the year, and the arrangements that we have made will enable us to make our readers familiar with the characteristic features of the gardens in each of the districts. We commence the series in this issue with an account of the horticultural features of the Isles of Scilly, and this will be followed by descriptions, even more freely illustrated, of the great gardening centres in South, West, East and North of England, and of the more important centres in Scotland and Ireland.

Garden Architecture cannot be omitted from any well considered scheme of garden adornment: we shall, therefore, present to our readers the best styles of Pergolas, Tea and Summer Houses, Terraces, Garden Vases, Garden Gates, Fountains, etc.; and these will be illustrated to show their suitability for the positions they occupy.

Rock, Water and Mural Gardening find many ardent lovers, and for these we shall cater extensively. Our success with these subjects in the past year, and the many new friends we have made as the result, have led us to make special preparations for illustrating the finest examples, and giving the best cultural details.

Hardy Flower Gardening, an all important and immensely popular subject, merits, and will continue to receive the fullest attention.

Profitable Cultures that are of special interest to the gardening community will be discussed by the best qualified to write upon the practical details as well as the general principles that must be carried out to secure success.

Roses and Carnations are among the most popular of garden flowers, and we shall continue to give them the prominence their beauty and usefulness demand.

Orchid Cultivation is now as essential a part of Horticultural Knowledge as Vegetable and Fruit Culture; we shall again have the services of eminently successful Culturists and Raisers, and from time to time we shall illustrate New Species, Hybrids and Varieties, and describe and illustrate the finest collections.

Chrysanthemums and Sweet Peas are of the utmost importance, and their selection and up-to-date methods of cultivation will be fully dealt with.

Hardy and Tender Fruit Culture is a branch of garden activity that *The Gardeners' Magazine* is especially *au fait* with. It has instituted many reforms, helped to build up a big industry, and will continue to urge extended cultivation in orchard, garden and glasshouse, on the most extended lines.

Plants and Flowers from Seeds are more important in these days than they were, and the means we have taken to bring more prominently before our readers the extreme value of Annuals and Biennials are certain to be appreciated.

The Kitchen Garden Department is of such importance that arrangements have been made with the most successful growers and exhibitors to contribute of their experience in these pages.

Novelties add zest to every branch of horticulture; in 1908 as in the past all the finest of them, whether tender or hardy, flower or fruit, useful or ornamental, will be described and figured with that promptitude which has won for us many admirers.

Scientific Horticulture, particularly in the direction of soil improvement, use of various manures, eradication of insect and other pests, prevention of fungoid attacks, and raising new and improved flowers, fruits, etc., will be given a prominent position.

Birds and Insects, and indeed all animal life that comes under the eye of the garden lover, because of good or evil deeds, will be discussed by competent naturalists.

Glass Houses: Their Construction, Heating, Ventilation, etc., will again receive the attention they demand, and full details of the best methods of providing good crops of flowers, fruits and vegetables, by their aid, will be given by leading gardeners of the day.

Every Saturday. **Price Twopence.**

*** If a receipt is required for amounts under 10s. a stamped envelope should be forwarded.

NOTES OF OBSERVATION.

◆

Leeks and Onions under Glass.—Almost every up-to-date gardener now raises these valuable vegetables under glass, in a temperature of about 50 degrees, and there is no question that the system is a sound one. What, however, I have noticed of late, is a tendency to sow the seeds altogether too thickly, and leave the seedlings in the same state. Only last year I saw a splendid box of seedlings ruined in this way; almost every plant damped off, and this at an amazing rate. With thin sowing, early pricking out, and thorough hardening off before planting, glass-raised leeks and onions are some of the most successful crops in the garden.—E. J. K.

Poinsettias after Flowering.—In view of the special treatment required by these plants, it is always well to keep them together after they have ceased to be beautiful. It should be remembered that much depends upon the gradual but thorough ripening of the stems, and to bring this hurriedly about is the reverse of wise. A place on a stage in full light, and with a temperature of about 50 deg., should, if possible, be given, and an effort should be made to keep the leaves on as long as possible consistent with allowing the plants to have a good rest. Where old stems are cut into short lengths for propagating purposes, there is no need to stand the resting plants under a stage when the leaves have fallen, as propagation in this case takes place much earlier than when green young shoots are used.—J.

Propagating Old Dracænas.—Large old dracænas are apt to be a bit of a nuisance in the stove at this season when room is precious; not only do they take up valuable space, but they shelter undesirable plant enemies. This being so, they should be taken in hand at the first opportunity, cut up, and used for propagating. Probably the tops are not worth saving, and if any doubt is felt on this point, throw them away, as they strike none too readily thus early in the year. With the stems and fleshy roots the case is different, and every piece of either, an inch long, may be depended upon to grow if placed in pans of light sandy soil, and stood on or near the hot-water pipes.—E. J. K.

Ornamental Asparagus. — A simple method of growing Asparagus plumosus and A. plumosus nanus, which are most useful for decorative purposes, is to train the shoots up a piece of twine. They can then be taken down when required, and used in various ways. Especially will this method of training be found the more useful during the next few weeks where house decoration has to be considered. In warm rooms, with a fair amount of light, it is surprising how long asparagus lasts in good condition. The long lengths may be twined wreathlike round any object, or along the edges of stands and baskets of plants with charming effect. If dwarf, bushy plants in pots are required for general decorative uses, the young growths should be pinched when they are about a foot high, and these will be found useful in vases for standing in exposed places in the dwelling-house. All species of asparagus are easily multiplied by division of the root-stock, and also by seed. If any plants have now become shabby, these may be treated as stated, and if put into small pots and given a free, rich loamy compost, and afterwards placed in a warm house, they will soon commence to grow and furnish material for next season's requirements.—B. CROMWELL, Cleveley Gardens.

Blind Deutzias.—The so-called blindness of deutzias is, in my experience, confined solely to forced plants, and consists, as most readers may know, of the production of flowers which never properly expand. I have known shoots over two feet in length, and covered with bloom buds, refuse to open a single flower. The general opinion is that this blindness is caused by introducing the plants suddenly to too much heat, and I believe that this is pretty correct in most cases. But there is another common cause of blindness, and one which I have seen in operation on quite a large scale. This is chopping off the roots at potting time. Plants are dug up from the open ground, and not only the roots, in some cases, but the bulk of the underground woody stock is cut away in order to get the plant into a small pot. Small wonder that the flowers refuse to open!—J.

Poinsettias.—Many of these will have had their floral bracts cut for Christmas decoration. They should be collected and placed in a warm, dry position, fully exposed to the light, and should not be placed, as is often done, underneath the stages, because they are unsightly. Mature wood, and plump eyes are what is required when the time for propagation arrives. Many failures occur in rooting poinsettias owing to the indifferent treatment the plants receive after the bracts have been cut, when a little care and attention bestowed upon them at the present time would ultimately lead to success.—B. CROMWELL, Cleveley Gardens.

A Rose-Potting Experiment.—The following incident may suggest ideas to some readers who are carrying out ground operations this winter. A few years ago an intelligent amateur gardener friend had to move a score or more of rose bushes in the course of winter ground work. In the ordinary way he would have heeled them in, and planted them again when the ground was ready. Instead, he carefully pruned in the roots, potted the plants, and plunged them in ashes outdoors until the turn of the year. He then took them to the greenhouse, pruned them, and obtained a nice lot of early flowers. Nor did his reward end here. After flowering, he planted the roses in a bed, and reaped a bountiful crop of autumn blooms.—E. J.

THE VALUE OF MUD.

Several of the old agricultural writers have advocated the utilisation of pond mud, and as a writer in "British Husbandry" (1837) observes: "The mud from ponds, when they are cleaned out, has always been an object of attention to farmers." The composition of the sediment may vary considerably, as will be seen from analyses given below, and is naturally dependent on the character of the pond. Where a pond is placed at the lower part of a field it is likely to receive, after rain, surface washings which may be rich in manure. If, however, the pond contains springs, the sediment may be of little or no value.

Pond mud has proved valuable at the Royal Botanic Gardens, Kew, where the deposit from the bottom of the lake has been used for some years past for general gardening purposes, as a dressing for the lawns, and also as a mulch for the beds, borders, and trees. It has also been used for such pot-grown plants as chrysanthemums, dahlias, fuchsias, pelargoniums, and other gross feeders. The best examples of calanthe and phaius (orchids) ever grown at Kew were planted in this mud. It is also an excellent soil for vegetables. As an example of how freely it may be used for trees, mention may be made of a mulch, four inches thick, which was placed last winter about the large horse chestnut near the Thames; the effect of this on the health of the tree is already most marked.

According to the "Journal" of the Board of Agriculture, the only plants for which it has not been found suitable are Ericaceæ and peat-loving plants generally. Probably this is due to the presence of calcium carbonate in the Thames water, from which the Kew lake is fed, and also to the shells of various molluscs which are abundant in the lake. The only harm that might possibly result from the use of this mud would arise if it were allowed to lie as a cake, so that air was excluded from the roots. The mud at Kew is the silt from the Thames water, and contains decomposed vegetable matter from the surrounding trees, etc.; when first taken out it has almost the consistency of clay, and in this condition is unsuitable for use. The practice at Kew is to drain off the water from the lake, and when the mud can be cut out with spades it is carried in barrows on to the banks, where it is allowed to lie and drain until it can be broken up easily. It is then distributed over the lawns, woods, beds, etc., where, under the influence of weather, it soon breaks down. If used on beds or borders it is forked over, and mixed with the other soil soon after it has been put on. For lawns it is used in the proportion of about twenty loads to the acre, it is then chain harrowed and raked, and after that it soon works down below the grass. When the lake was first cleaned out in 1892 to 1894 the mud was found to be five feet deep in some parts, and altogether some thousands of loads were removed.

An analysis has been made of the mud taken from the Kew lake, and also of some pond mud from Nottinghamshire. The sample from Kew contained 45.15 per cent. of moisture, and that from Nottinghamshire contained 78.81 per cent.; in order to enable them to be compared, the results are given in the following table, free of moisture:

	Sample from Kew. per cent.		Sample from Notts. per cent.
Organic matter* and loss on heating	11.30	...	27.71
Oxide of iron and aluminium	8.17	...	10.45
Lime	12.04	...	7.79
Magnesia, alkalies, etc.	0.97	...	7.05
Carbonic acid	8.85		
Phosphoric acid	0.27	...	0.32
Insoluble siliceous matter	58.40	...	46.68
Total	100	...	100
*Containing nitrogen	0.439	...	0.863
Equal to ammonia	0.533	...	—

It will be seen that the Kew sample in its dry state had less than half the quantity of vegetable matter (and nitrogen derived therefrom) contained in the other. It had, however, more lime and nearly as much phosphoric acid. The fact that the one sample contained so much less water than the other would make the Kew sample in its natural state the richer of the two. The quantity of lime would make it a useful material for any land where lime is needed.

Two other samples of mud from ponds in Kent are referred to in the fifth report of the Analytical Laboratory at the South-Eastern Agricultural College, Wye. Sample A was from a pond which had not been "mudded" since 1836, and as neither ditches nor drains run into it, the water supply has been kept up only by percolation through the soil, which is described as a sandy clay. For many years the pond had, throughout the summer, been a mass of weeds, mainly silk weed, and Nymphæa alba. The analysis showed this mud to contain 23.3 per cent. of water, 7.8 per cent. of organic matter, and .183 per cent. of nitrogen.

Sample B was from an adjacent pond, into which a little ditch and several drains run. It was expected that the mud would be very rich, and it was used as a dressing for hops. Analysis showed, however, that mud was little, if any, richer than the soil of the hop garden, and it had not, therefore, much value as a fertiliser. It is mentioned in the report that "The fermentation processes going on at the bottom of a pond are very complete, organic matter is broken up into carbonic acid, marsh gas, and hydrogen, and free nitrogen is probably liberated also. Resistant forms of organic matter would survive, but these have little value as manure." The analysis showed this sample to contain 52.2 per cent. of water, 7.3 per cent. of organic matter, and .175 per cent of nitrogen.

Generally speaking, the effect of such material is as much a physical or mechanical one as a chemical one, and if used on land of lighter and drier texture would help in improving it. On heavy land, on the other hand, it might not be so successful. It should do very well as a top-dressing for grass.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

ADDRESS.—O. C., Ramsgate: The hon. secretary of the National Sweet Pea Society is Mr. C. H. Curtis, and his address is Adelaide Road, Brentford, Middlesex.

ANNUAL MEETING OF THE ROYAL HORTICULTURAL SOCIETY.—M. E., Billericay: The annual meeting is always held in February, and the next is due on February 11.

STEWING PEARS.—G. S., Mortimer: The best stewing pears are Uvedale's St. Germain, Catillac, Bellisime d'Hiver, Verulam, and General Todleben. The latter is not always fit for dessert, but it is a good stewing pear.

PROPAGATING FUCHSIAS.—S. L. A., Salisbury: Towards the end of the month place a couple of old plants of each variety in gentle heat. Here they will soon commence to grow, and the young growths may then be removed and inserted in sandy soil in pots or boxes, surfacing the soil with sand after the cuttings have all been inserted.

LARGE ONIONS.—S. B., Bury St. Edmunds: Sow the seeds thinly now in boxes of fine rich soil, and place in gentle heat. When the seedlings appear keep them near the glass, and gradually harden them off so that by April they will be fit to plant out into the well-prepared ground. Onion fly rarely damages crops so raised.

BOXES FOR EXHIBITION ROSES.—S. R. S., Exeter: Exhibition rose boxes must be four inches high in front, and eighteen inches wide, and of the following lengths (all outside measurements): For 24 blooms, 3ft. 6in. long; for 18 blooms, 2ft. 9in. long; for 12 blooms, 2ft. long; for 9 blooms, 1ft. 6in. long; for 6 blooms, 1ft. long; for 8 trebles, 3ft. 6in. long; for 6 trebles, 2ft. 9in. long; for 4 trebles, 2ft. long.

FORCING FIGS IN POTS.—B. M., Gloucester: By far the best method of forcing figs is to place the pots in a bed of tree leaves made up on the stage of a light house. The bed should be at a temperature of about 70 degs. The temperature of the house, until growth begins, should range from 50 to 55 deg. at night, and 55 to 65 deg. by day. When the fruits begin to swell, gradually raise the night temperature to 60 deg., and the day temperature to 70 deg. Syringe the trees and paths and stages with tepid water once or twice a day, according to the weather prevailing. Do not force up the temperature by excessive firing in cold weather.

HYBRIDISING.—A. T. C., Huntingdon: A knowledge of elementary botany is essential to success in hybridisation. Many who profess to scoff at botanical study have themselves acquired such elementary knowledge at second-hand, but they frequently fail in hybridising because they do not understand the affinities of plants, and their experiments are about as likely to succeed as a cross between a cat and an elephant.

SPOTTED MIMULUSES.—A. D. G., Epsom: The modern strains of these interesting and beautiful plants are vastly superior to the old ones; it is therefore essential that a first-rate strain be secured. Sow the seed about the middle of February in gentle heat; gradually harden off the seedlings and plant them out in April or May. So treated the plants will flower well the same year and afterwards. Being hardy and perennial they will stand the winters in all but very cold, wet soils.

HEADING BACK TREES.—G. R. D., Oxford: This work should be done as soon as weather permits. If the trees are tall and the branches heavy, the work must be done with great care, or there may be considerable damage to property and person. In wet weather, in snow, or during hard frost, tree lopping or heading is dangerous, as it also is during high winds. Get the lopping done directly weather permits; the removal of the wood may wait until all the trees are headed back.

SEEDLING PERNETTYAS.—A. R. S., Bangor: As you will not require a large quantity, gather the best fruits from the best varieties, and pick out the seeds, rubbing them through dry sand to clean them. Sow them in a shallow bed of light peaty soil made up in a cold frame, or in boxes of similar soil placed in a frame. Sow in February or March, thinly and regularly, and as the seedlings progress give them plenty of air, and when they are large enough transfer them to a nursery bed during genial and moist weather.

SINGLE CHRYSANTHEMUMS.—F. E. G., Nottingham: The single varieties that gained a first-class certificate from the National Chrysanthemum Society in 1906 were: Surrey (Wells and Co.), J. H. Runchman (Wells and Co.), Alice Crate (Wells and Co.), Lizzy (W. Pagram), Beauty of Weybridge (W. Pagram), Mrs. H. Redden (H. Redden), Crown of Gold (W. Pagram), Miss E. Partridge (Wells and Co.), Galatea (Wells and Co.), Edith Harling (Wells and Co.), Kathie (Peed and Son), Mrs. Thyne (D. Fairweather), and Mrs. Andrews (D. Fairweather). The Royal Horticultural Society granted an Award of Merit to Dora Godfrey (W. J. Godfrey), Mrs. Brewster (D. Fairweather), Edith Harling (Wells and Co.), Merstham White (Wells and Co.), and Miss H. Hampson (E. Beckett).

CLEANING WATER COURSES.—G. W. C., Sunbury: The matter requires careful handling, and it is better to try all other means of securing the end in view before taking legal steps. We believe sections 14 and 15 of the Land Drainage Act of 1847 (10 and 11 Vict., c. 38), cover your inquiry. According to the Board of Agriculture Section 14 of the Act enacts that where, by the neglect of any occupier to maintain or join in maintaining the banks, or to cleanse and scour or join in cleansing and scouring the channels of existing drains, streams, or water-courses lying in or bounding the lands of such occupier, injury is caused to any other land, the proprietor or occupier of any land so injured may serve a notice on the neglecting occupier requiring him to maintain the banks or cleanse or scour the channels in question. If he neglects so to do, the occupier of the land injured may, after one calendar month from the service of the notice, carry out the necessary work. The cost of the same or a just proportion thereof is to be paid by the neglecting occupier, and payment may be enforced by an order of justices. Section 15 provides that, unless the drain, stream, or water-course to be cleansed bounds or immediately adjoins the land of the occupier injured by the neglect, a justices' warrant to enter on the defaulter's land in order to carry out the necessary works must be obtained. This warrant is to be granted if the justices are satisfied that the injury has been caused by the neglect of the occupier whose land is to be entered.

NAMES OF PLANTS.

Under this heading we can only undertake to name species and well marked varieties of plants, and not florists' flowers. Specimens should be packed in stout boxes with damp (not wet) moss, or some leaves, as packing material, to ensure their reaching us in a fresh state. It is essential that flowers must accompany specimens of flowering plants, that fern fronds be fertile, and that numbers be firmly attached to the specimens so that they can be seen without any untying. We cannot promise to name more than six specimens at one time from any one correspondent.

M. J. B., Effingham.—1, Azara microphylla; 2, not recognised.

S. P. M., Grantham.—1, Psychotria cyanococca; 2, Ardisia crenulata.

R. S., Leicester.—1, Genista fragrans; 2, Calceolaria Burbidgei; 3, Asparagus Sprengeri.

C. L. T., Cardiff.—1, Mussænda frondosa; 2, Choisya ternata; 3, Jasminum nudiflorum; 4, Gaultheria procumbens.

FORTHCOMING ENGAGEMENTS.

WEDNESDAY, January 8.—Society of Arts Meeting, 8 p.m.
TUESDAY, January 14.—Royal Horticultural Society. Floral, Fruit, and Orchid Committees, 12 noon; Scientific Committee, 4 p.m.; General Meeting, with Lecture, 3 p.m.
WEDNESDAY, January 15.—Society of Arts Meeting, 8 p.m.
THURSDAY, January 16.—Linnean Society Meeting, 8 p.m.
TUESDAY, January 21.—National Amateur Gardeners' Association Annual Meeting, 7 p.m.
WEDNESDAY, January 22.—Society of Arts Meeting, 8 p.m.
TUESDAY, January 28.—Royal Horticultural Society Meeting of Floral, Fruit, and Orchid Committees, 12 noon; Scientific Committee, 4 p.m.; General Meeting, with Lecture, 3 p.m.
WEDNESDAY, January 29.—Society of Arts Meeting, 8 p.m.

Autumn - planted Cabbages and Slugs.—I never remember seeing autumn-planted cabbages so badly mauled by slugs as they have been this winter. No doubt the mild, open weather of the early winter enabled these pests to keep on the prowl longer than is their wont, but the fact remains that in many cabbage plots nothing but bare stumps can now be seen. Fortunate is the man who has a reserve to draw on, or who can buy more, for there is little doubt that plants put in now stand as good a chance as many put in in October.—E.

SWEET PEAS FOR WINTER.

A light house of the modern type and well prepared solid beds, at or near the ground level, are the best conditions for the culture of sweet peas for winter cutting. Too many cultivators are under the impression that any kind of soil is good enough for this crop, while no crop pays better for a thoroughly sound and well prepared rooting medium.

When a succession of flowers is looked for sow at intervals from the end of August until October, and for flowers to come in early before the outside crop is ready sow the first week in the New Year. If the beds are ready, the seed can be sown directly into them; otherwise small pots should be prepared and about three seeds sown in each, thinning them down subsequently to single plants and planting them out before the pots are filled with roots. Avoid breaking the ball when planting, and place a small stake to each immediately, even if strings are to be used to support the vines, for often there is a shrinkage of the soil that takes the plants down with it and strangles them at the point where they are fed.

The watering at first must be gone about with considerable caution, many cases in which the plants stubbornly refuse to grow being directly traceable to overwatering. All through the growing season cool, airy conditions are necessary. Fire heat should be avoided as long as possible unless damp and wet weather prevails, when a little heat should be kept on and full ventilation to keep the atmosphere dry and the air moving about the plants. The temperature is not an important point, provided there is plenty of air kept on at all times, day and night, when possible. From 48 degrees to 50 degrees is the best night temperature, rising a few degrees by day when dull, and, of course, higher by sun heat. Try, in short, to maintain an atmosphere as near like that obtaining outside, and as little artificial as may be. If this point were kept in mind, there would be less trouble with bud dropping than is often the case. Sudden changes of temperature, too much fire heat, and fluctuations of root moisture, are all prolific causes of bud dropping.

Frequent attention to supporting the vines is necessary, and the closest attention must be given to insects. Greenfly often attacks the young points of the shoots. If possible, get rid of it by frequent light sprayings with nicotine in solution, but if this is found to be ineffectual, fumigate lightly on two successive evenings. Heavy fumigating is very injurious to sweet peas, especially in the early stages. The green grubs of the white butterfly are also destructive early in the season, and should be picked off daily. Later they usually give little trouble. When the time comes for gathering the flowers, do this carefully, and avoid injuring the vines.—R., in "Gardening" (American).

Radishes on Vine Borders.—Vine and peach borders are such sacred things in some gardeners' eyes that to suggest sowing radishes on them savours of heresy. However, the plan is such a good one that I do not hesitate to recommend it to anyone who values early radishes—or the delicious greenery which comes before the radish does—and has not a spare pit in which to grow them. The seed should be scattered broadcast and just buried by breaking down the soil with a rake; a soaking of water should follow, unless the border is already wet. The radishes should be thinned early, eating the thinnings like mustard and cress, none should be left to grow old.—E. J. K.

GARDENER (Head, where three or four are kept); married; age 37; life experience in large establishments; excellent testimonials; 5 years present situation. AYERS, Keevil, Trowbridge, Wilts.

A GENTLEMAN wishes to strongly recommend his HEAD GARDENER; leaving through place being sold; experienced in all branches; age 39; married, two in family; excellent references. JACKSON, Holme Park, Rotherfield, Sussex.

GENERAL LORD GRENFELL highly recommends HEAD WORKING GARDENER, Butler's Court Gardens, Beaconsfield, Bucks; thoroughly experienced in all branches. Inside and Out; married, no family; age 37. Apply Lord GRENFELL, Royal Hospital, Dublin.

THE HON. EVELYN HUBBARD strongly recommends E. S. WILES as HEAD GARDENER or GARDENER-BAILIFF; over 30 years' experience, Inside and Out, early and late forcing, land and stock; hard working, and absolutely trustworthy; 13 years' reference. Address The Rookery, Downe, Kent.

SITUATION as HEAD GARDENER; age 30; married. Address C. HARRIS, Bath Road, Eastington, near Stonehouse, Glos.

GARDENER (Single-handed, with help); 6½ years' experience as Foreman in last place; death cause of leaving; single, age 32; excellent references. G. EUSTON, Shrubs Hill, Suning Dale, Ascot, Berks.

GARDENER (good Single-handed or with help); thorough experience Inside and Out; good references; age 31; married, no family. E. THURGOOD, The Cottage, Mayfield, Earlswood, Surrey.

GARDENER (Single-handed, or with help); 12 years' experience Inside and Out; excellent reference; abstainer; married when suited. R. WISBEY, care of J. K. Fitch, Esq., Woodside, Muswell Hill.

GARDENER (good Single-handed or with help); married, no family; abstainer; disengaged 25th of January. G. HAMBIDGE, Summer Court Lodge, Wrotham, Kent.

FOREMAN (Inside or Out); 14 years' experience in general routine of well-kept establishments, including House and Table Decorations; good references as to personal character and ability. A. ENGLISH, Culham Court Gardens, Henley-on-Thames, Berks.

FOREMAN (General) or GARDENER (Second). Inside and Out, where four or more are kept; fourteen years' general experience; single, age 27. HILLS, Bochanger Cottages, Kennington, Ashford, Kent.

RICHARD SMITH and CO., LTD., beg to announce that they are constantly receiving applications from Gardeners seeking Situations, and that they will be able to supply any Lady or Gentleman with particulars, etc. St. John's Nurseries, Worcester.

YOUTH (18) desires SITUATION as IMPROVER on Nursery; has had experience in Palms, Ferns, Begonias, etc.; make himself generally useful; good references; abstainer. TALBOT, 20, Manor Park, Lee, S.E.

YOUNG MAN, who has served his time in General Nursery desires Situation as Improver; has had experience in Chrys., Ferns, and General Bedding stuff; large nursery preferred. F. E. PARK, 7, Radstock Road, Fairfield, Liverpool.

SITUATION COUPON

To the Advertisement Manager of "THE GARDENERS' MAGAZINE,"
148 & 149, Aldersgate Street, London, E.C.

For JAN. 18, 1908.

Please Repeat my Advertisement.

NOTES OF THE WEEK.

Nature Study in Schools.

Having for a long series of years kept constantly before those engaged in educational work the importance of giving Nature study a prominent place in the curriculum of both elementary and secondary schools, it is highly gratifying to have unquestionable evidence that our views are now accepted by the whole of the scholastic world. We have, as opportunities have arisen, urged that children should be taught something about the animate and inanimate life with which they are brought into daily contact. We have pointed out that such knowledge would be far more useful to them than would be a superficial acquaintance with the abstruse subjects that for so long a time found favour with educational authorities. Not less consistent have we been in our advocacy of the necessity in teaching botany, of making the children familiar with the various parts of the plant selected for study by means of living specimens, instead of setting them the irksome task of committing to memory lists of cumbersome and, to them, unintelligible scientific terms. An acquaintance with these latter is essential to those who desire to make a serious study of botany, but to attempt to set children to learn them before they know practically anything of those parts of the plants to which they refer was a grave mistake, inasmuch as it had the effect of rendering the study of botany distasteful to young people. Happily this is now changed, and a more rational method of procedure adopted. The great change that has taken place in the views of educationalists on the position botany should have in the school curriculum, and on the methods of teaching, was brought into prominence at the Conference of School Teachers held in London a few days since. We heard nothing about the necessity for children being taught scientific terms, but we had evidence that all the speakers were agreed that the children should study the plants from living specimens, and, where practicable, from specimens growing in the borders in the garden or in the field. Dr. Forman, who presided over the two meetings devoted to Nature study, in opening the discussion on the teaching of botany, said that, while botany was not specifically mentioned in the Government Code, it was included in science and Nature study. In many schools in the Metropolis the subject was taught, as shown by the fact that in the County Council schools 16,841 pupils were taking botany, and in the non-provided schools the number was 2,332. He thought that, with a somewhat crowded curriculum, the botanical course should not be too systematic or too detailed. The lessons should be demonstrations rather than lectures, and be recreations to be enjoyed rather than tasks to be performed. It was not, he said, advisable to frighten children with scientific terms or bring into prominence the difficulties that beset students who determine to carry their studies to an advanced stage. Facilities, he said, were afforded the pupils engaged in botanical studies to visit the botanical gardens in the Metropolitan parks with their teachers for the purpose of observation lessons on botany and Nature study. They would, he had no doubt, have classes in both the Royal and municipal parks, but they could not, in Dr. Forman's opinion, teach botany by lectures. If they were to obtain the best possible results from the teaching they must, he felt, avoid places where the plants were arranged in their natural orders, and had labels attached to them. To bring about a real love of Nature they must, said Dr. Forman, familiarise the children with the country itself. There can be no doubt as to the advisability of familiarising children with the country, but in the interest of children in London and large provincial towns this view must not be pressed too far. Several other speakers referred to the advantage of using living specimens, and of taking the pupils into public parks and gardens in towns, and of making excursions into the fields and lanes in the country, and the desirability of avoiding everything of the dry-as-dust character.

REV. W. WILKS, M.A.
Secretary of the Royal Horticultural Society.

Rev. W. Wilks. — In presenting our readers with a portrait of the Rev. W. Wilks, which we do with much pleasure, we are met with the difficulty that in the space at our disposal we cannot do even bare justice to the valuable service he has rendered in the cause of horticulture during the long period he has filled the position of secretary of the Royal Horticultural Society. The name of Mr. Wilks is so intimately associated with the society as we now know it, that one might be excused were one to indulge in the supposition that it was chiefly of his creation. We do not suggest that, because, if for no other reason, we know that it would be most distasteful to Mr. Wilks to have other than the barest acknowledgment of his services in our reference to him. No one knows better than himself, and no one is more ready to acknowledge the self-denying labours of the distinguished horticulturists with whom he has been associated in the management of the Royal Horticultural Society, which now occupies a position that surpasses in influence, in usefulness, and in wealth, any other society associated with gardening in the world. With a full knowledge of the strenuous efforts made by the several members of council to perform their duties we shall not write a word that can in any way be regarded as comparative. All have unquestionably done their best; but speaking, as we shall do, in the most moderate manner, we must in this brief reference to Mr. Wilks, give expression to our opinion, which is shared by all who know him that it would be difficult if not impossible, to overestimate the value of his share of the great work that has been accomplished in placing the Royal Horticultural Society in the commanding position it holds. We know from long experience that the success of a society largely depends upon its secretary. We know also that a secretary with commanding ability, with exceptional capacity for sustained effort, and with great strength of will, must exercise a potent influence upon the progress of a society. Mr. Wilks possesses these three important attributes in a marked degree, and as they have been exercised to the fullest extent with but one object in view—the welfare of the society—he has very materially contributed to the success that has been achieved in the conduct of its affairs. If it be asked what is the measure of this success? A reply can be given in a few words. When about twenty years ago Mr. Wilks accepted the responsibilities of his present office the Royal Horticultural Society was in debt, practically homeless, and with a small number of Fellows. Now, it has a large sum of money invested, a magnificent hall, a well furnished library, a finely equipped lecture room, adequate offices, a large experimental garden, and over 10,000 Fellows. To have taken a small part in bringing about such splendid results would be something to be proud of; but to have had an important share—well, we suppose Mr. Wilks is too engrossed in his multifarious duties to think about such a matter, and we will not do more than express a hope that the Royal Horticultural Society may long continue to have the advantages of his services.

Horticultural Club.—The next house dinner of the Horticultural Club will take place on Tuesday next, the 14th inst., when Mr. E. A. Bunyard will give a lecture on "Recent Advances in Plant Breeding," with special reference to Mendel's work.

Cankered (?) Rose Roots.—At the meeting of the R.H.S. Scientific held on December 31, a report was received from Mr. Güssow concerning the rose roots shown at the previous meeting by Mr. Jenkins, as follows: "I find the trouble with the rose roots is not canker, and cannot be transferred from one plant to another. It is generally accepted that canker is caused (a) by frost, (b) by fungus, (c) by any other mechanical injury which fungi have infested. In the present case there is no fungus present, and if the root in the attacked plant (when repotting) is cut away, no injury will be done to the plant. The growth is nothing but a continuous formation of adventitious roots, especially where the root is bent or injured. New callus is formed, and from that callus rootlets are everywhere sent out, but as the plant depends on the root system of the Manetti no use is made of these roots, and they develop but little.

Some Famous Horsham Gardens.—The district of which the old Sussex town of Horsham is the centre, has long been famous for its great gardens, and in the issues of the GARDENERS' MAGAZINE for February 8 and 15 we shall give a fully illustrated account of the more noteworthy of them. Among other gardens that will be described and illustrated are Leonardslee, Warnham Court, South Lodge, and Denne Park.

Weather of 1907.—The record of the weather of the past year contains several features of interest. Somewhat generally regarded as a wet year, the observations of the Meteorological Office show that the rainfall was below the average. The aggregate rainfall was 19.5 inches, or 4.9 inches below the average for the past thirty-five years. The year was distinguished by the number of days on which rain fell, and this frequency of rainy days gave rise to the supposition in the minds of many that it was a wet one. There were one hundred and sixty-two rainy days, and of these twenty-two occurred in October, in which month, singularly enough, the rainfall was nearly half an inch below the average. So great a frequency of rainy days suggests a deficiency of sunlight, and undoubtedly the weather was sufficiently dull in the early part of the year to increase the difficulties with which those engaged in flower and fruit culture under glass have to contend. But, as a matter of fact, there was an increase of ninety in the number of hours of sunlight, the total having been 1,234 hours. With regard to temperature, the mean was 50.2 degrees, or 0.1 degree above the average. The highest monthly mean was 60.8 degrees, in August, and the lowest 38.5 degrees in February. The highest temperature was 80 degrees in September, and the lowest 23 degrees in January. The mean temperature for the summer months was below, and for the winter months above the average.

Grease Bands and Winter Moth.—Messrs. W. Voss and Co., of Millwall, contributed to the last meeting of the R.H.S. Scientific Committee specimens of grease bands taken from trees on Mr. Mitchell's fruit farm, Enfield Highway, covered with both male and female specimens of winter moth (brumata). The bands had been placed on the trees in the middle of November, and no other insects but these had been caught with the exception of two or three weevils. The chairman remarked that the time of appearance of this moth varied greatly with the seasons, frequently being found as early as near the beginning of October. Grease banding to be thoroughly efficient should, it was pointed out, be commenced then, and the bands should be kept sticky until near the end of March in order to capture other species of a similar nature.

Chrysanthemum Leaf-Mining Fly.—In the course of last autumn specimens of chrysanthemums were received by the Board of Agriculture from Newmachar, Aberdeen, and it was found that they were infested with the maggots of a leaf-mining fly. The fly has since been bred out from the material sent, and has been identified as Phytomyza geniculata (=P. horticola). This fly has a similar life history to the celery fly (Acidia heraclei), and the measures most suitable for dealing with that pest should be practised in the case of P. geniculata. It may be remarked that this fly can also breed in the sow thistle (Sonchus oleraceus), and this is an additional reason why this weed should be eradicated. An ichneumon fly parasitic on the maggots of P. geniculata was also bred out from the specimens sent.

Sweet Pea Trials at Reading College.—The National Sweet Pea Society purposes holding a further trial of sweet peas at the University College Gardens, Reading, during 1908, and is desirous that growers and raisers should assist in making these trials as complete as possible by sending seeds of new sweet peas that they may be distributing in 1908, or are getting forward for distribution in 1909. The trial will be an absolutely independent one, and under the able management of Mr. Charles Foster. Not fewer than fifteen seeds of each variety should be sent, and they should reach Mr. Charles Foster, Assistant Director in Horticulture, University College, Reading, on or before January 14, 1908. The Colour Section to which each variety belongs, and whether it has waved or plain flowers, should be indicated. The committee does not propose to make a charge for these trials, but suggests that a donation be sent to the honorary secretary, Mr. C. H. Curtis, Adelaide Road, Brentford, to help defray their cost. The trials conducted in 1907 necessitated considerable expenditure, and this was defrayed chiefly by private donations. No awards to new varieties will be made at the society's exhibitions in 1908; Awards of Merit or First Class Certificates will be granted only to meritorious varieties tested in the society's trials at Reading.

List of Kew Publications.—The appendix to the "Kew Bulletin," containing the list of Kew Publications, 1896-1906, is of special interest, as illustrating the activity of the several members of the staff of the Royal Gardens in dealing with plant nomenclature and other matters of botanical and horticultural interest. In the "Kew Bulletin" for 1897 a list was given of publications by members of the Kew staff, or by other botanists working at Kew, which appeared during the period from the first devotion of the Royal Botanic Gardens to public use in 1841 till the close of the year 1895. That list, compiled with much care by Mr. B. Daydon Jackson, takes the form of a chronological catalogue, and it has proved so useful that it has seemed desirable to the authorities to bring the subject matter up to date. The chronological method of arrangement, so valuable as to be practically essential in a catalogue covering a period so prolonged as that dealt with in the list drawn up by Mr. Daydon Jackson, has been considered less necessary when what is little more than a decade is passed under review. It has therefore been possible to make use in the present list of the convenient system of classification by authors, under whose names are catalogued (i.) separate works, (ii.) contributions to separate works, and (iii.) articles in scientific and technical journals, given in each case in chronological sequence. The practical utility of the list will, it is hoped, be found to have been considerably enhanced from the fact that in cases where authors have made themselves responsible for the proposal of previously undescribed species this is duly indicated.

Sulphuric Acid as a Fungicide.—We learn that a safe and useful fungicide, which is used with satisfactory results at the Royal Gardens, Kew, is a solution of sulphuric acid in the proportion of 1 to 1,000, or 1 lb. to 100 gallons. This does not injure the plant, and completely destroys mildew and similar fungi. No harm will be done to pumps, etc., if a small amount of clear water is pumped through the apparatus at the conclusion of spraying. This should be done whatever solution is used, as the apparatus is then left in a clean condition.

The Fire Thorn.—A correspondent resident in Surrey, who does not wish his name to be published, sends us a finely fruited spray of Leland's pyracantha (Cratægus pyracantha Lelandi), with a note stating that it was cut from a large specimen growing against the walls of his residence. He also expresses the opinion that it is one of the finest of the berry-bearing shrubs for clothing wall spaces. We fully share in this expression of opinion, and should be prepared to go further, and suggest that it is the very best for the purpose. Leland's pyracantha is vigorous in growth when planted in ordinary soil, has evergreen foliage, is attractive in spring when enwreathed in its white flowers, and is highly effective when the fruits that follow have assumed their characteristic brilliant orange colour. This fine shrub has been rather freely planted in gardens in the Kew Gardens district, and one has excellent opportunity for instituting comparisons between the different styles of training that have been adopted. In some cases the shrubs are regularly trained over the walls of the houses, and the lateral growths annually shortened back to within about six inches of the wall, and these bear good crops of fruit, and produce a bright effect. In other cases one, two, or three main stems are trained up the wall at various distances apart, and the lateral growths are allowed to grow naturally away from the wall. These latter produce the largest crops of fruit, and the shoots depend more or less gracefully. The colour display is not brighter than that produced by the severely trained examples owing to the mingling of the foliage with the fruits, but owing to the relief given by the green leaves the effect is far more pleasing. To prevent the growths extending too far from the wall a portion of them are cut back each year. Grown as bush and pyramidal specimens in the shrubbery border this thorn fruits freely, and produces a fine effect, but the birds begin to levy toll upon the fruits early in the winter when the plants are some distance from the house, and if the the weather is severe soon take the crop.

Prevention of the Cabbage Flea.—Two or three years since experiments were carried out in Germany for the purpose of testing measures recommended for the prevention of the Cabbage Flea (Haltica oleracea). Among them, dusting the plants with tobacco dust is mentioned as satisfactory. During the past year this pest has been very troublesome in Germany, and this remedy has given excellent results on a large area of white cabbage, to which it was applied at the rate of rather less than 3 cwt. per acre. Four days after the application none of the insects could be found, nor did they appear again subsequently. It is mentioned that successful results can only be expected in dry weather, as rain would wash the tobacco dust into the ground.

Legible Writing is at all times desirable, but it is especially so when sending an order for goods required for the garden. Our attention is called to this by an advertiser in the Gardeners' Magazine, who writes: "Our advertisement is bringing us a large number of orders, and among these is some that are most difficult to decipher. Some customers do not give their names, and others omit the post town, with the result that we are not always able to execute their order immediately; in fact, not until they write again."

A USEFUL AUTUMN PEAR.

While unquestionably a matter of considerable importance that fruit growers should carefully consider the merits of new kinds as they are presented to public notice, and add to their collections such varieties that have the promise of proving valuable additions, it is most desirable that the older kinds of proved usefulness should not be overlooked. Hence it may be well that we should remind our readers of the extreme value of Louise Bonne of Jersey, which for nearly a century has contributed liberally to the autumn fruit supplies. We are induced to refer to it not because of it being superior in appearance and quality to some others of its season, but because of its adaptability to gardens of small size and to soils and districts of the most varied character. It can be successfully grown over extremely wide areas, and in proof of this we would mention that we have seen in the North Riding of Yorkshire crops that would compare most favourably with those borne by trees growing in Kent.

Louise Bonne of Jersey is not only so accommodating as to be equally at home in both the southern and northen counties, but it may be successfully grown in almost any form the cultivator may desire. It is one of the best pears for growing as bushes and pyramids, and it produces excellent crops when grown as a standard. The fruits are of medium size, and decidedly handsome, while the quality leaves little to be desired, the flesh being white and buttery, and the flavour delicious. Excepting in the northern districts the fruits have in favourable seasons a bright crimson cheek, and this colouring adds much to their appearance when on the table. It ripens in October.

PEAR LOUISE BONNE OF JERSEY.

One of the most useful of dessert pears, ripening in October.

NEW AMERICAN TREE CARNATIONS.

Several new American varieties of tree carnations were sent out last spring, and among them is one named Aristocrat, described as bright cerise, a shade brighter than Mrs. Lawson. In its form, stem, habit, and size, one grower describes it as nearer perfection than any carnation of to-day. If this is so it must differ with him from what it has done with me. It is possible that when we have propagated our own stock, and grown it another season, it may have the good qualities attributed to it. Under artificial light it is very effective. Winsor is a variety which promises well. It is silvery-pink, and the colour improves after the blooms are fully open. It has a good full flower, calyx and stem good, and apparently it is a good grower. The colour is a useful shade for winter; this variety and Beacon are the most promising of those we have on trial this season.

Melody is a pale pink sport from Mrs. Lawson, and has the same shaped bloom as the parent, and similar habit; this may improve another season, but so far it is a trifle disappointing.

Helen Gould, a sport from Enchantress, with fine pencillings of carmine on silvery pink, has been simply Enchantress in bloom and growth with me, but I saw some good blooms of this variety at Chelsea recently, fully bearing out the catalogue description; like most sports this will probably vary at times, and therefore must not be judged too quickly. Imperial, "a variegated variety of delicate pink, similar to Enchantress" (vide catalogue description) has not yet opened its blooms; it is a strong grower. Pink Imperial is said to be a pink sport from the preceding variety, its growth is similar to that of Imperial, but its colour I should describe as rosy-magenta, and not at all pleasing. I may be colour blind, but it requires a great stretch of imagination on my part to describe this variety as pink, indeed, it is misleading to send out varieties of this shade and call them pink.

The unsatisfactory varieties of this season may improve after becoming acclimatised, but in my opinion this batch is not much improvement on previous introductions. Have our American friends reached perfection in their tree carnations?

I think that with the material now at the command of English growers, they may raise varieties more suitable for our winter cultivation under glass than some of the American varieties have proved to be. There is one good English variety which has done remarkably well with me, viz., Mrs. H. Burnett. I think Mr. Burnett may be congratulated on raising this beautiful carnation which fully bears out his description.

T. H. SLADE.

Poltimore Gardens.

White Scale on Palms.—This disfiguring pest often works for months unnoticed along the midribs on the underside of palm fronds, and it is often only when a palm becomes decidedly unhealthy that its presence is detected. More than this, I have even known young fellows sponge a palm several times during a season without observing the scores of scales clustered along its lower midribs. Ordinary sponging avails nothing against the pest; it may kill off a few tender young ones, but the old scale is generally totally unmoved by the sponge. A piece of pointed stick is the thing, bamboo for preference, and with this every scale should be dislodged, after first well syringing the plant to make the pests slide off easily. A good sponging should follow the use of the stick.—E. J. K.

SPECIALISING IN THE FLOWER GARDEN.

The interest of a garden is immensely increased if the owner makes a speciality of some particular flower; that is, spares neither reasonable trouble nor expense to grow some one flower, and as many of the best varieties of it as possible, to the highest state of perfection. Some make a speciality of some particular flower under glass, and some of a half-hardy plant in pots out of doors, such as fuchsias, but the most common practice, because it makes less demand upon the accommodation at disposal, is with some hardy flower in the open ground. A nobleman who has a seat in the Eastern Counties makes a speciality of the blush-white Souvenir de Malmaison carnation, and has seven or eight houses filled with plants. It is very delightful to have a supply of this lovely flower for several months of the year, but it will occur to the real garden-lover that so much space, time, and expense might be used in providing greater variety, and therefore greater interest.

Suggestions for specialising under glass are endless, but it is with hardy flowers that this article proposes to deal. Under glass the conditions can be made to suit almost any plant, but in the open many things have to be considered, one's absolutely favourite flower being not infrequently out of the question through unsuitability of conditions. As the flower should have as nearly perfect conditions as possible, it is necessary, before any decision is arrived at, to give due consideration in relation to the situation and nature of the ground to be devoted to it. If the soil is very sandy, and becomes hot in the summer, it would be simply courting failure to attempt specialising with roses, dahlias, perennial phloxes, pyrethrums, or pæonies, while carnations, iris, narcissi, and the choice aquilegias might, with due preparation of the soil, do well. On the other hand, if the soil is very heavy and wet, to take another extreme, it would only lead to disappointment to take in hand the lilies, carnations, narcissi, and anemones, while great success might be obtained with pæonies, pansies, pentstemons, and Lenten roses. This is speaking in a general way, for it is possible, and even practicable, in dealing with a limited tract of ground, to very largely alter its character, though its wetness or dryness, heaviness or lightness, will only be modified. It is hardly necessary to say that deficiency of chalk or potash, phosphates, or humus, can be remedied by deep cultivation and intelligent manuring, though not all at once.

Another thing which has to be taken into consideration is the aspect of the ground. It would be of little use to make a large collection of pansies or perennial phloxes on a piece of ground sloping towards the south, with little or no shade, and as little use to make a cistus or carnation garden on a northern aspect sheltered by trees or buildings. Still another consideration is the garden which lies low near a river, large tract of water, or marshy ground, as in a low-lying garden, especially if near much water there is a risk of late spring frosts injuring the occupants. Moreover, a humid atmosphere, which is fatal to many plants in winter that elsewhere are quite hardy, e.g., pentstemons and antirrhinums are more or less injured. It is only by taking all the above considerations into account when selecting a flower for extensive growing that the best results can be obtained, results which are a constant source of pleasure to oneself and the envy of all one's neighbours and visitors. Is the inspiring of this harmless envy in our neighbours a pardonable weakness among gardeners?

Hence the selection of a particular flower is not necessarily the one we like most, but the one out of half a dozen favourites to which our conditions are best suited. The expense of forming a good collection of varieties of any one subject is certainly very considerable if done all at once. In looking through a catalogue of a well-known nurseryman, I found there 270 named varieties of iris, 230 of pæony, 120 of herbaceous phlox, 90 of Michaelmas daisy, 80 of pyrethrum, and 65 of Lenten rose. As most of these are at least a shilling each, and many of them half a crown or more, it will be readily seen to what expense one can go with one flower only. But this is not necessary, and those not disposed to spend very much can have a splendid show by beginning with a few varieties and propagating them, and exchanging with friends, and what is most interesting, by raising seedlings. Raising iris, Michaelmas daisies, or pæonies from seed, is a very different thing to raising lobelias, stocks, or verbenas. In the latter case we know pretty much what we are going to obtain, but in the other case there is so much sporting that you can have no idea how the seedlings will come, nine out of ten of little value probably, but the tenth may be really valuable if the seed has been saved from good varieties.

The position in the garden which such special collections should take must, of course, depend upon the taste of the owner as much as upon the nature of the garden. To the lover of flowers, beds packed with pelargoniums, like magnified window-boxes, and rainbow borders of ageratums, geraniums, calceolarias, etc., are a source of very little interest. The eye, having glanced over them once, finds little more in them to engage its attention. With a pæony, briar rose, or carnation and lily garden, how different it is, not only in the season of their flowering, but from the commencement of spring! The one objection to be brought against such specialising is that the part of the garden devoted to one thing is generally only gay for a comparatively short time, generally only from one to two months. Each must deal with this objection to suit his own special circumstances. Why not apply to the garden the principal applied to general knowledge—everything of something and something of everything?

When one has the necessary space, and is prepared to spend the necessary amount of money upon it, one could have special gardens in beauty at each season of the year — Lenten roses or primroses in March, narcissi or pansies in April and May, pæonies or irises in June, carnations or lilies in July, or phloxes or pentstemons in August, and Michaelmas daisies or border chrysanthemums in September and October. This would be a large order, more suited to a nurseryman than to a private individual.

This article has already exceeded its proper length, or I should like to have said something about the fascination of making a study of one flower, and hybridising selected blossoms with a view to getting new varieties. This is very delicate work and a never failing source of interest.

ALGER PETTS.

Sweet Pea "Annual" and Schedule.—We are asked to state that the National Sweet Pea Society's "Annual" and Schedule for 1908 will be sent to members about January 16.

NEW PLANTS, ETC.

◆

CYPRIPEDIUM MOONBEAM.

A very fine Lady's Slipper, with bold, substantial flower, set on a rather short stiff stem. The parents are C. Thomsoni and C. Sallieri. As seen in the illustration on p. 15, the dorsal sepal has a broad white apex, with green and purple shading, and veins running into it from the base. The petals and lip are yellowish green with brown shading, and these organs are brightly burnished. F.C.C., R.H.S., December 31, 1907. Mr. Alexander, orchid grower to Major Holford, Westonbirt, Gloucester.

CYPRIPEDIUM TROILUS CRAVENIANUM.

A large-flowered variety of the hybrid between C. insigne Harefield Hall and C. nitens, Ball's var. As may be expected from such a cross, the variety much resembles C. i. Harefield Hall. The dorsal sepal is large, white and green, with dull purple spots; the lip and petals are green, shaded with brown. A.M., R.H.S., December 31, 1907. Mr. J. H. Craven, J.P., Beeches, Keighley, Yorks.

ODONTIODA CRAVENIANUM.

A very beautiful hybrid obtained by crossing Odontoglossum cordatum and Cochlioda Noetzliana. The flowers are neat and medium size, borne on a short, slender spike. They are brilliant scarlet, with faint mottlings of dull yellow on the lip, though one or two flowers also showed very subdued markings on the petals. A.M., R.H.S., December 31, 1907. Messrs. Charlesworth and Co., Heaton, Bradford.

PRIMULA OBCONICA GRANDIFLORA HAYES' PLACE DOUBLE.

We protest against the use of such names as this—they detract from the merit of good plants, and soon sink into disuse. The strain shown represented an excellent and double type of P. obconica in several shades of rose and lilac. The strain is worthy of extensive culture. A.M., R.H.S., December 31, 1907. Mr. E. Hambro, Hayes' Place, Kent.

POTATO FAVOURITE.

This excellent kidney potato was sent up from Wisley, where it has passed the trials, and the cooking test in fine style. F.C.C., R.H.S., December 31, 1907. Messrs. Dobbie and Co., Rothesay.

GESNERA CARDINALIS.

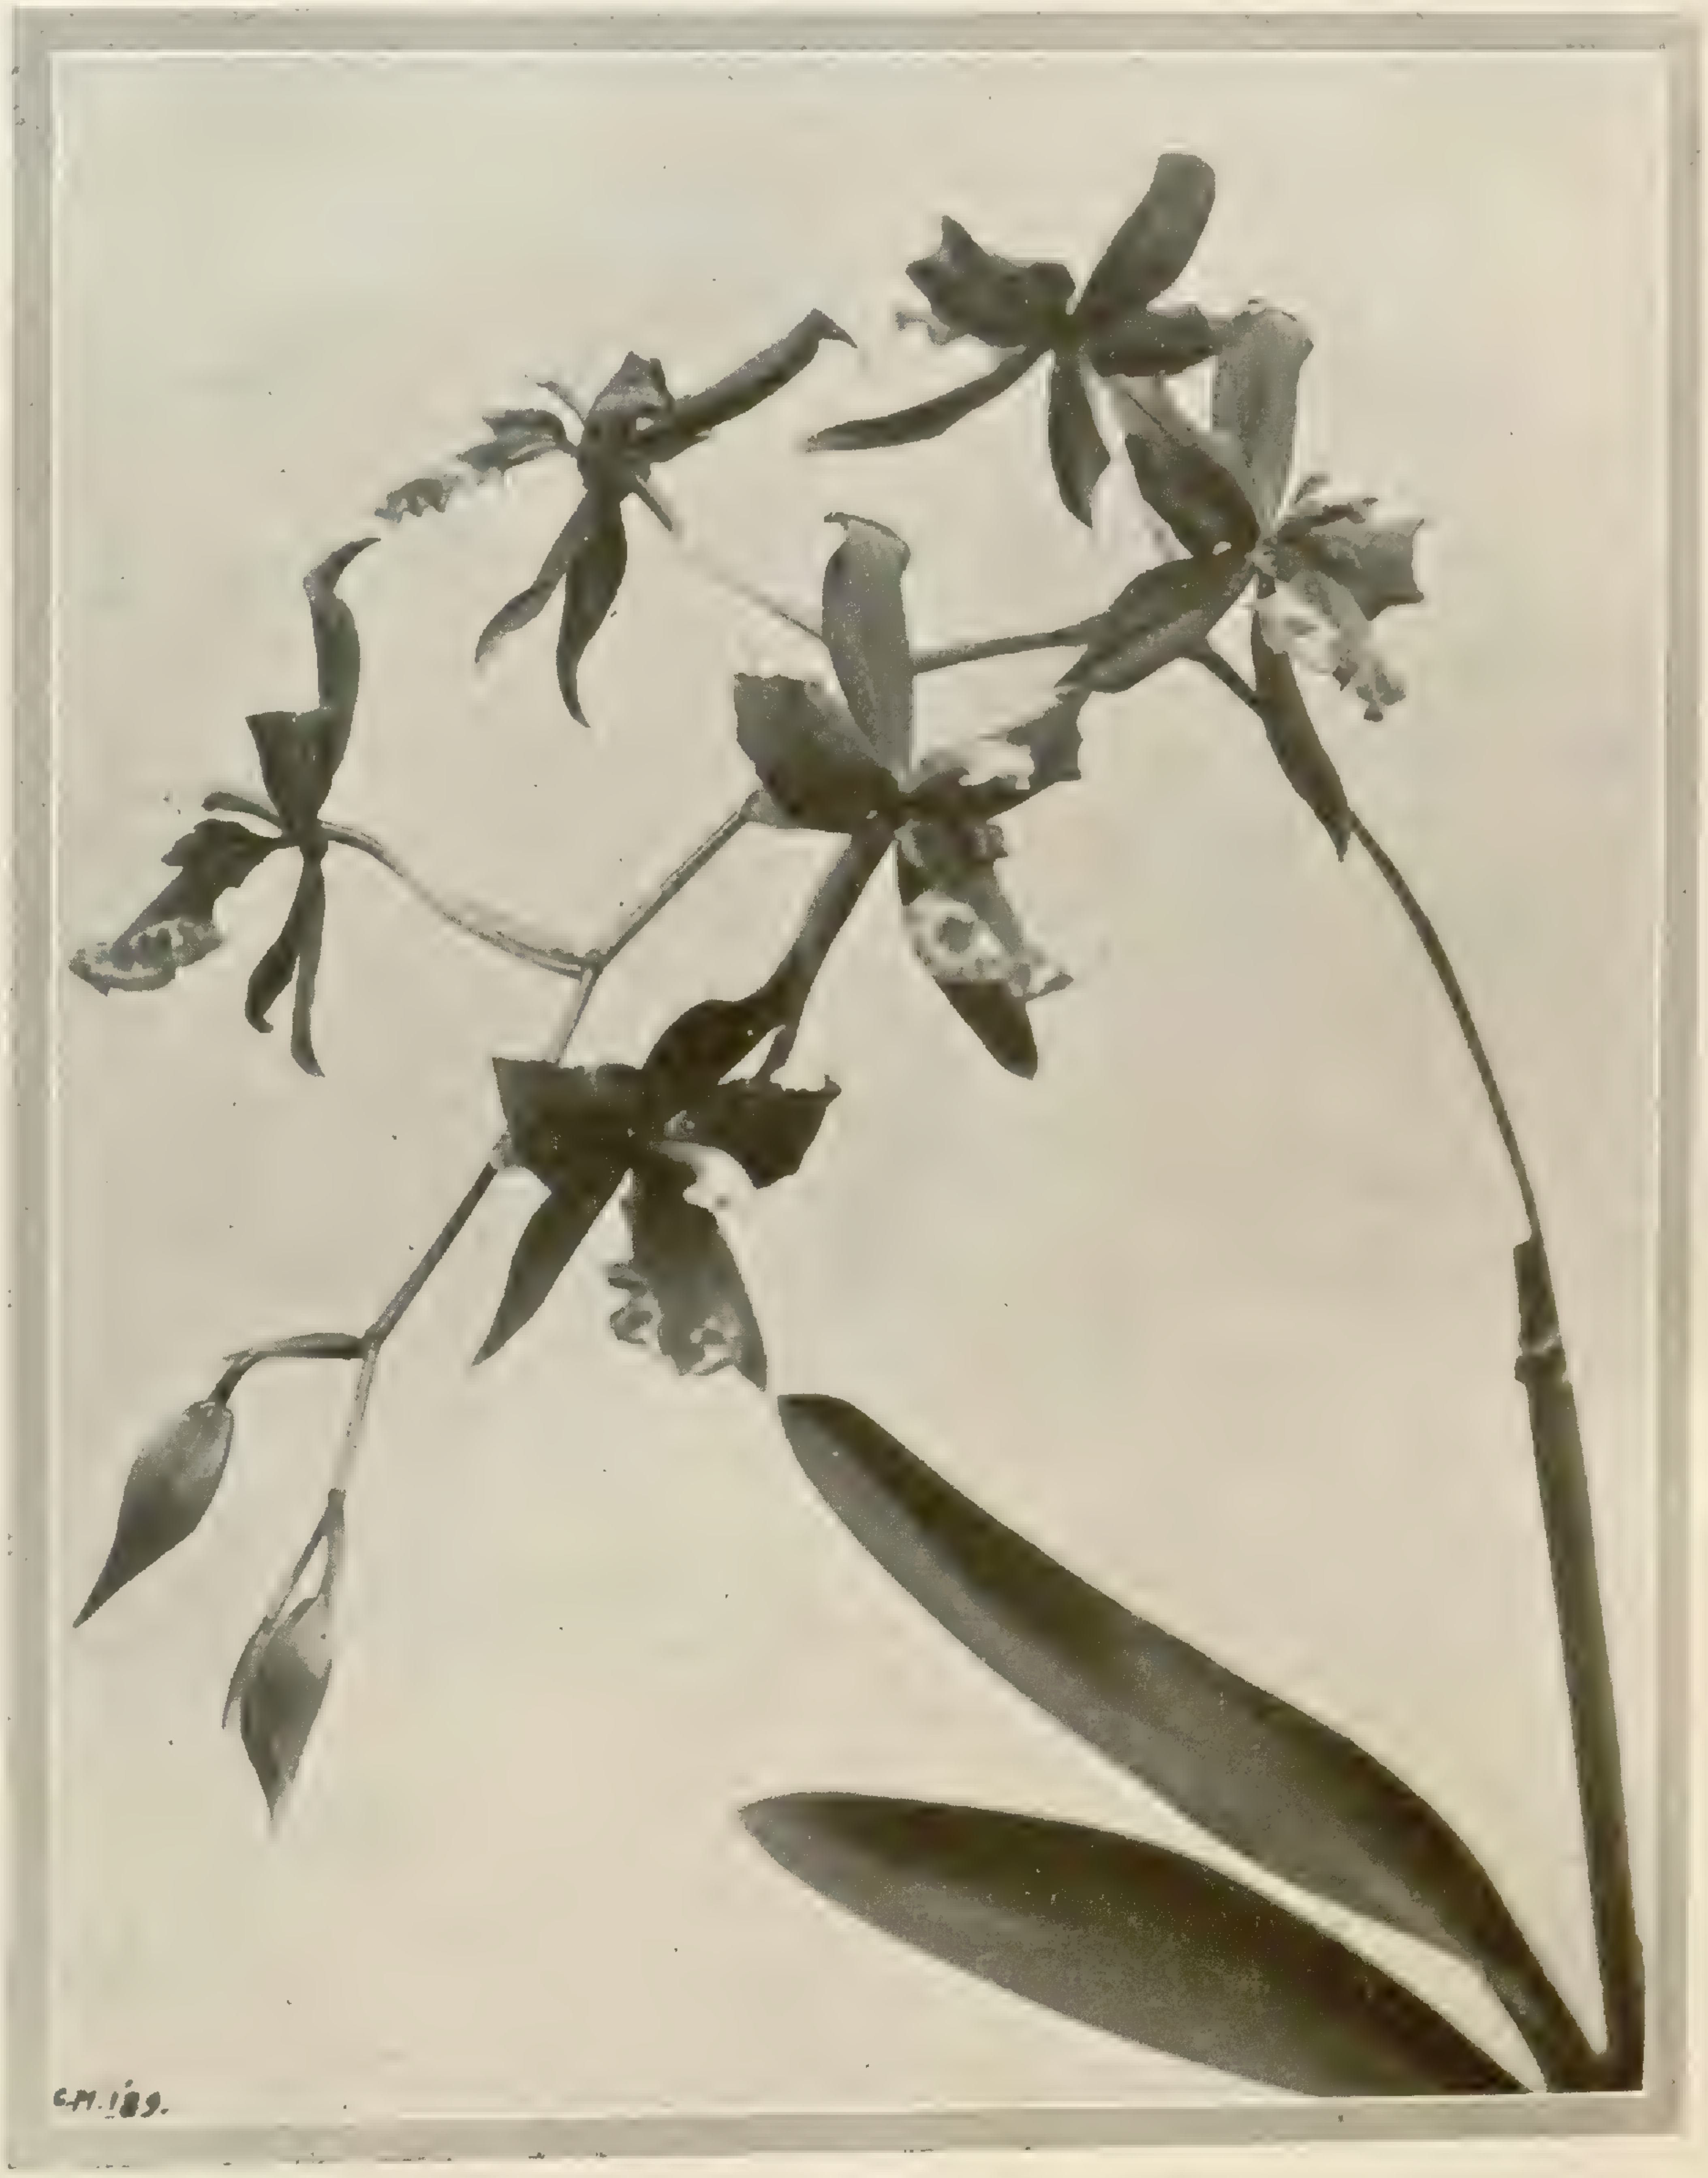
This handsome species, which has long been in cultivation, belongs to the group of species for which Decaisne proposed the genus Dircæa. The most striking characteristic of the group is the marked disproportion between the upper and lower lips of the corolla, that on the lower side being very short. In common with other gesneras the species has a tuberous root, and under ordinary good cultivation attains to a height ranging from eight to ten inches. The leaves are broadly ovate, bright green, and the flowers are produced in a cluster at the top of the stem. These latter are between two and three inches long, and bright red-scarlet. It is, in Mr. Watson's opinion, the best of the gesneras from the decorative standpoint, and is quite easy of culture to those who understand the cultivation of stove plants.—"Bot. Mag.," t. 8167.

PRIMULA MUSCARIOIDES.

This striking primula is a native of Western China, and is very closely allied to P. cernua, P. deflexa, and P. pinnatifolia, and at first was taken for P. deflexa, which, however, has fewer and larger flowers, and at Kew attains to a greater height. The flowers are produced in dense heads, turn downwards, and are deep purple-blue, the colour becoming paler towards the tips of the lobes; the leaves are similar in shape to those of the common primrose. Mr. G. Forrest describes it as growing in moist, open, grassy situations on the margins of pine forests in Yunnan.—"Bot. Mag.," t. 8168.

PICEA MORINOIDES.

A handsome fir, of which there appears to be but two specimens in the United Kingdom. One of these is growing at Castlewellan, co. Down, the seat of the Earl of Annesley, which was raised from seed received from Chumbi in 1889. The other is in the gardens of Leonardslee, Horsham, the seat of Sir Edmund Loder, Bart., and must, judging from its large size, have been planted many years since. This tree has produced cones for the first time in this country. P. morindoides is conical in growth, with spreading branches and slender, pendulous branchlets, the leaves slender, yellowish-green when young, becoming greyish-green with age.—"Bot. Mag.," t. 8169.



ODONTIODA CRAVENIANUM.

Flowers deep rich red scarlet, with yellow mottlings on the lip.

ERIA LONGISPICA.

An interesting species, which has been in cultivation at Kew during the past ten years or so. It is a free-growing species, nearly allied to D. latifolia, with erect habit, broad leaves, and long spikes of very numerous flowers, which are light yellow blotched with reddish-purple. Although possessing comparatively little horticultural interest, it is not wanting in attractiveness when so well grown as in the case of the Kew specimen. This is grown in a tropical house in a mixture of peat and sphagnum, kept moist at all times, except for about eight weeks in midwinter, when the plant is allowed to rest.—"Bot. Mag.," t. 8171.

DELPHINIUM CANDIDUM.

An interesting species belonging to a small group of delphiniums confined to the mountains of tropical East Africa. It is closely allied to D. Leroyi and D. macrocentron, and has large, pure white flowers with purple anthers and sweetly scented, the perfume resembling that of the primrose; the leaves are palmately five-lobed, and measure four or five inches across the widest part. The plant figured in the "Botanical Magazine" was raised in the gardens of Hindlip Hall, from seed gathered by Lady Hindlip in 1904 between Mount Elgon and Kisumu, Uganda. D. candidum is a perennial species, and dwarf in growth. —"Bot. Mag.," t. 8170.

Summer Bedding.—If the plan of summer bedding has not yet been arranged, it should be done without delay, and in due course the stock of plants be worked up accordingly. It is, of course, much better to prepare the plants according to requirements than to fill the beds according to the plants at hand. If only a small number of stock plants are available, early propagation will be necessary to ensure obtaining sufficient. As the annual seed catalogues have been sent out the order should at once be made up and despatched, as a number of seeds for summer bedding may with advantage be sown in the course of this month. In purchasing seeds it is always best to order from a good firm, even if the cost is apparently a little more, it being much better to start with good strong seedlings of the finest types. A few novelties should be selected and tried each season, and thus ensure keeping abreast of the times.—E. F. Hazelton, Knowsley Gardens, Prescot.

GROUPING CONIFERS.

No garden of any size is complete without a good collection of coniferous trees, for at all seasons of the year they are most interesting. In some it may be their peculiar growth, in others their foliage, while not a few produce cones of exceptional beauty.

If we take the different sections of Abies, in these alone we have sufficient material to form quite an interesting pinetum, some of them being so dwarf when fully grown as to scarcely exceed a couple of feet in height, while others grow so rapidly that in the course of a few years they make valuable timber. Though many of the pygmy conifers can only be regarded as botanical curiosities for planting in small gardens, there are others of noble dimensions that are worthy of, not only being planted as single specimens or forming collections, but extensive cultivation for the supply of timber.

To plant a pinetum worthy of the name would need much space and an undulated piece of land, and this cannot be provided in all places, though much might be done in this direction on many estates if sufficient interest were taken in the subject, and a thorough knowledge of their requirements forthcoming. I remember a choice collection of coniferous trees being planted on an estate, with such species as the Common Spruce, Pinus austriaca and other quick growing kinds being planted amongst them for shelter while they were young. As the common kinds grew more rapidly than the choice ones, and as there was a change in the management of the estate, the person appointed knowing nothing about conifers had all the choice slow ones cut down, the majority of those left being of little or no value.

For a person to take an interest in these trees he must be brought up amongst them, and must study their habits as an orchid grower does all the peculiarities of the plants under his charge, and know the requirements of each. Some kinds, in fact the majority of them, succeed best on a sloping piece of land where the water can pass away rapidly, as few of them will succeed in low swampy ground. Where such a position cannot be provided, the land ought to be drained, and the trees raised well above the level of the ground to give them a start.

Firs.

Some of these are close, compact growing trees, having a spread of only a few feet, while others need plenty of room for them to develop freely. Such species as Abies amabilis, A. concolor, A. grandis, A. nobilis, A. lasiocarpa, A. Nordmanniana, A. bracteata, and others of like habits are upright growing trees, and of themselves do not require planting more than forty feet apart for the display of their characteristics, even when fully grown.

It is a mistake to plant such trees at regular distances apart, better by far group them more naturally, at the same time giving them plenty of room. What could be more effective than a group of Pinus sylvestris, planted irregularly, when they have attained to the age of from eighty to a hundred years? At that age the trunks and bark have become interesting, the lower branches having died away. As a rule, however, the silver fir, if allowed to grow naturally, given ample space, will retain its branches down to the ground even at a greater age, if the grass around it has been kept short and the plants free from weeds.

In addition to the foregoing kinds of firs, there are others of the spruce family which are most interesting. Picea pungens glauca, A. polita, A. Smithiana, A. Engelmanni, and A. Alcockiana may be mentioned, all of which grow well on light soil in a fairly dry situation. Here, too, such species as the Douglas fir, Abies, and A. Albertiana thrive admirably.

Pines.

Those who have noticed a patch of waste land on the edge of a forest will, in all probability, have been attracted by the young seedlings, and notice how they have grown in irregular patches. In some places, close to the forest, they will be clustered together, in others they stand out more singly. It is this kind of growth that gives a natural beauty to the landscape, and if in planting for ornament something of this kind were attempted, the effect in after years would be far more pleasing than is an artificial arrangement. Some of the least spreading kinds might be planted at irregular distances closer together, giving such species as Pinus insignis a space of at least fifty feet from anything else. This is a kind that does not grow well everywhere, but here it is sheltered from the north, and has already attained a height of upwards of a hundred feet. There are many interesting trees in this group, some of them of rapid growth, while others are much less so. When trees of P. Cembra, P. strobus, P. pyrenaica, P. sylvestris, P. Laricio, P. macrocarpa, and P. ponderosa, and the like have attained to a height of a hundred feet, and having stems from six to ten feet in circumference they are certainly noble objects.

Cedars.

Cedars have been associated with our gardens for a long number of years, and there are some truly noble specimens in various parts of the kingdom. Those at Wilton Park, near Salisbury, are very fine, as also are those at Goodwood, Stowe, and other places. Here Cedrus deodara grows very rapidly, trees planted about half a century ago have already attained a height of upwards of one hundred feet, having trunks from nine to ten feet in circumference. The difference in the colouring of the foliage of some of the varieties is very great. Cedrus atlantica aurea, whose young foliage is of a rich golden yellow, forms a great contrast to that of C. atlantica glauca, and the various forms of C. deodara, some of which have quite a silvery hue. Unfortunately these trees soon grow too large for small gardens, and are more adapted for park planting, or in places where there is ample room for them to show themselves to advantage. Though single specimens present a noble appearance when they are old a group of half a dozen or so of the different varieties when young is far more pleasing, and these may be kept within bounds for a number of years by taking out the points of the leading shoots each year, thus causing them to assume a more conical habit.

Cupressus.

For small gardens there is such a variety of cupressus that very fine, interesting groups may be formed of these, and if we add to them the junipers and retinosporas there is hardly any end to the variety. Some are dark green, others a bluish cast, while some are yellow, and others almost white. If we take the cupressus alone, there is sufficient variety in them to satisfy most people, and, as most of them are of slow growth they are a long time in growing too large for a limited space. It is, moreover, as young trees that they are the most effective. C. Lawsoniana lutea, when about twenty feet high, is a handsome tree of upright habit. So is C. L. Goveniana, but when these become overgrown they are liable to be broken down by heavy falls of snow, and then their beauty is spoiled. Amongst the junipers, Juniperus chinensis aurea, J. japonica aurea, and J. virginiana glauca are most effective when planted amongst the greener foliaged kinds, and such that turn a brown colour in the autumn. The colouring is sufficiently varied for a very pleasing combination to be formed in a limited space. Such kinds are most effective when planted in large beds in winter, as their neat habit and varied colours render them most attractive.

Miscellaneous.

Of course, there are many other conifers that are very interesting, some of them, such as the taxodiums, the Wellingtonias, and yews, being quite as ornamental in their way as any others. Then again there is the thuias, of which T. Lobbi is certainly worthy of special mention, particularly when well grown on a lawn where the grass is kept short, for then it is seen at its greatest beauty. Plants from eighty to one hundred feet high, with their slender tapering leads feathered to the ground are objects not soon to be forgotten. There is also a small group known by the name of Libocedrus. Where these do well they are very ornamental, but L. chilensis is often cut back in severe winters except in very sheltered places, and therefore not to be generally recommended. Here it was quite killed in 1880-1881, but L. decurrens is a noble tree, and quite hardy. A very interesting little group is formed by the podocarpus, but with us they do not grow satisfactorily, as only two or three of the species are sufficiently hardy to withstand the winter in this low-lying place.

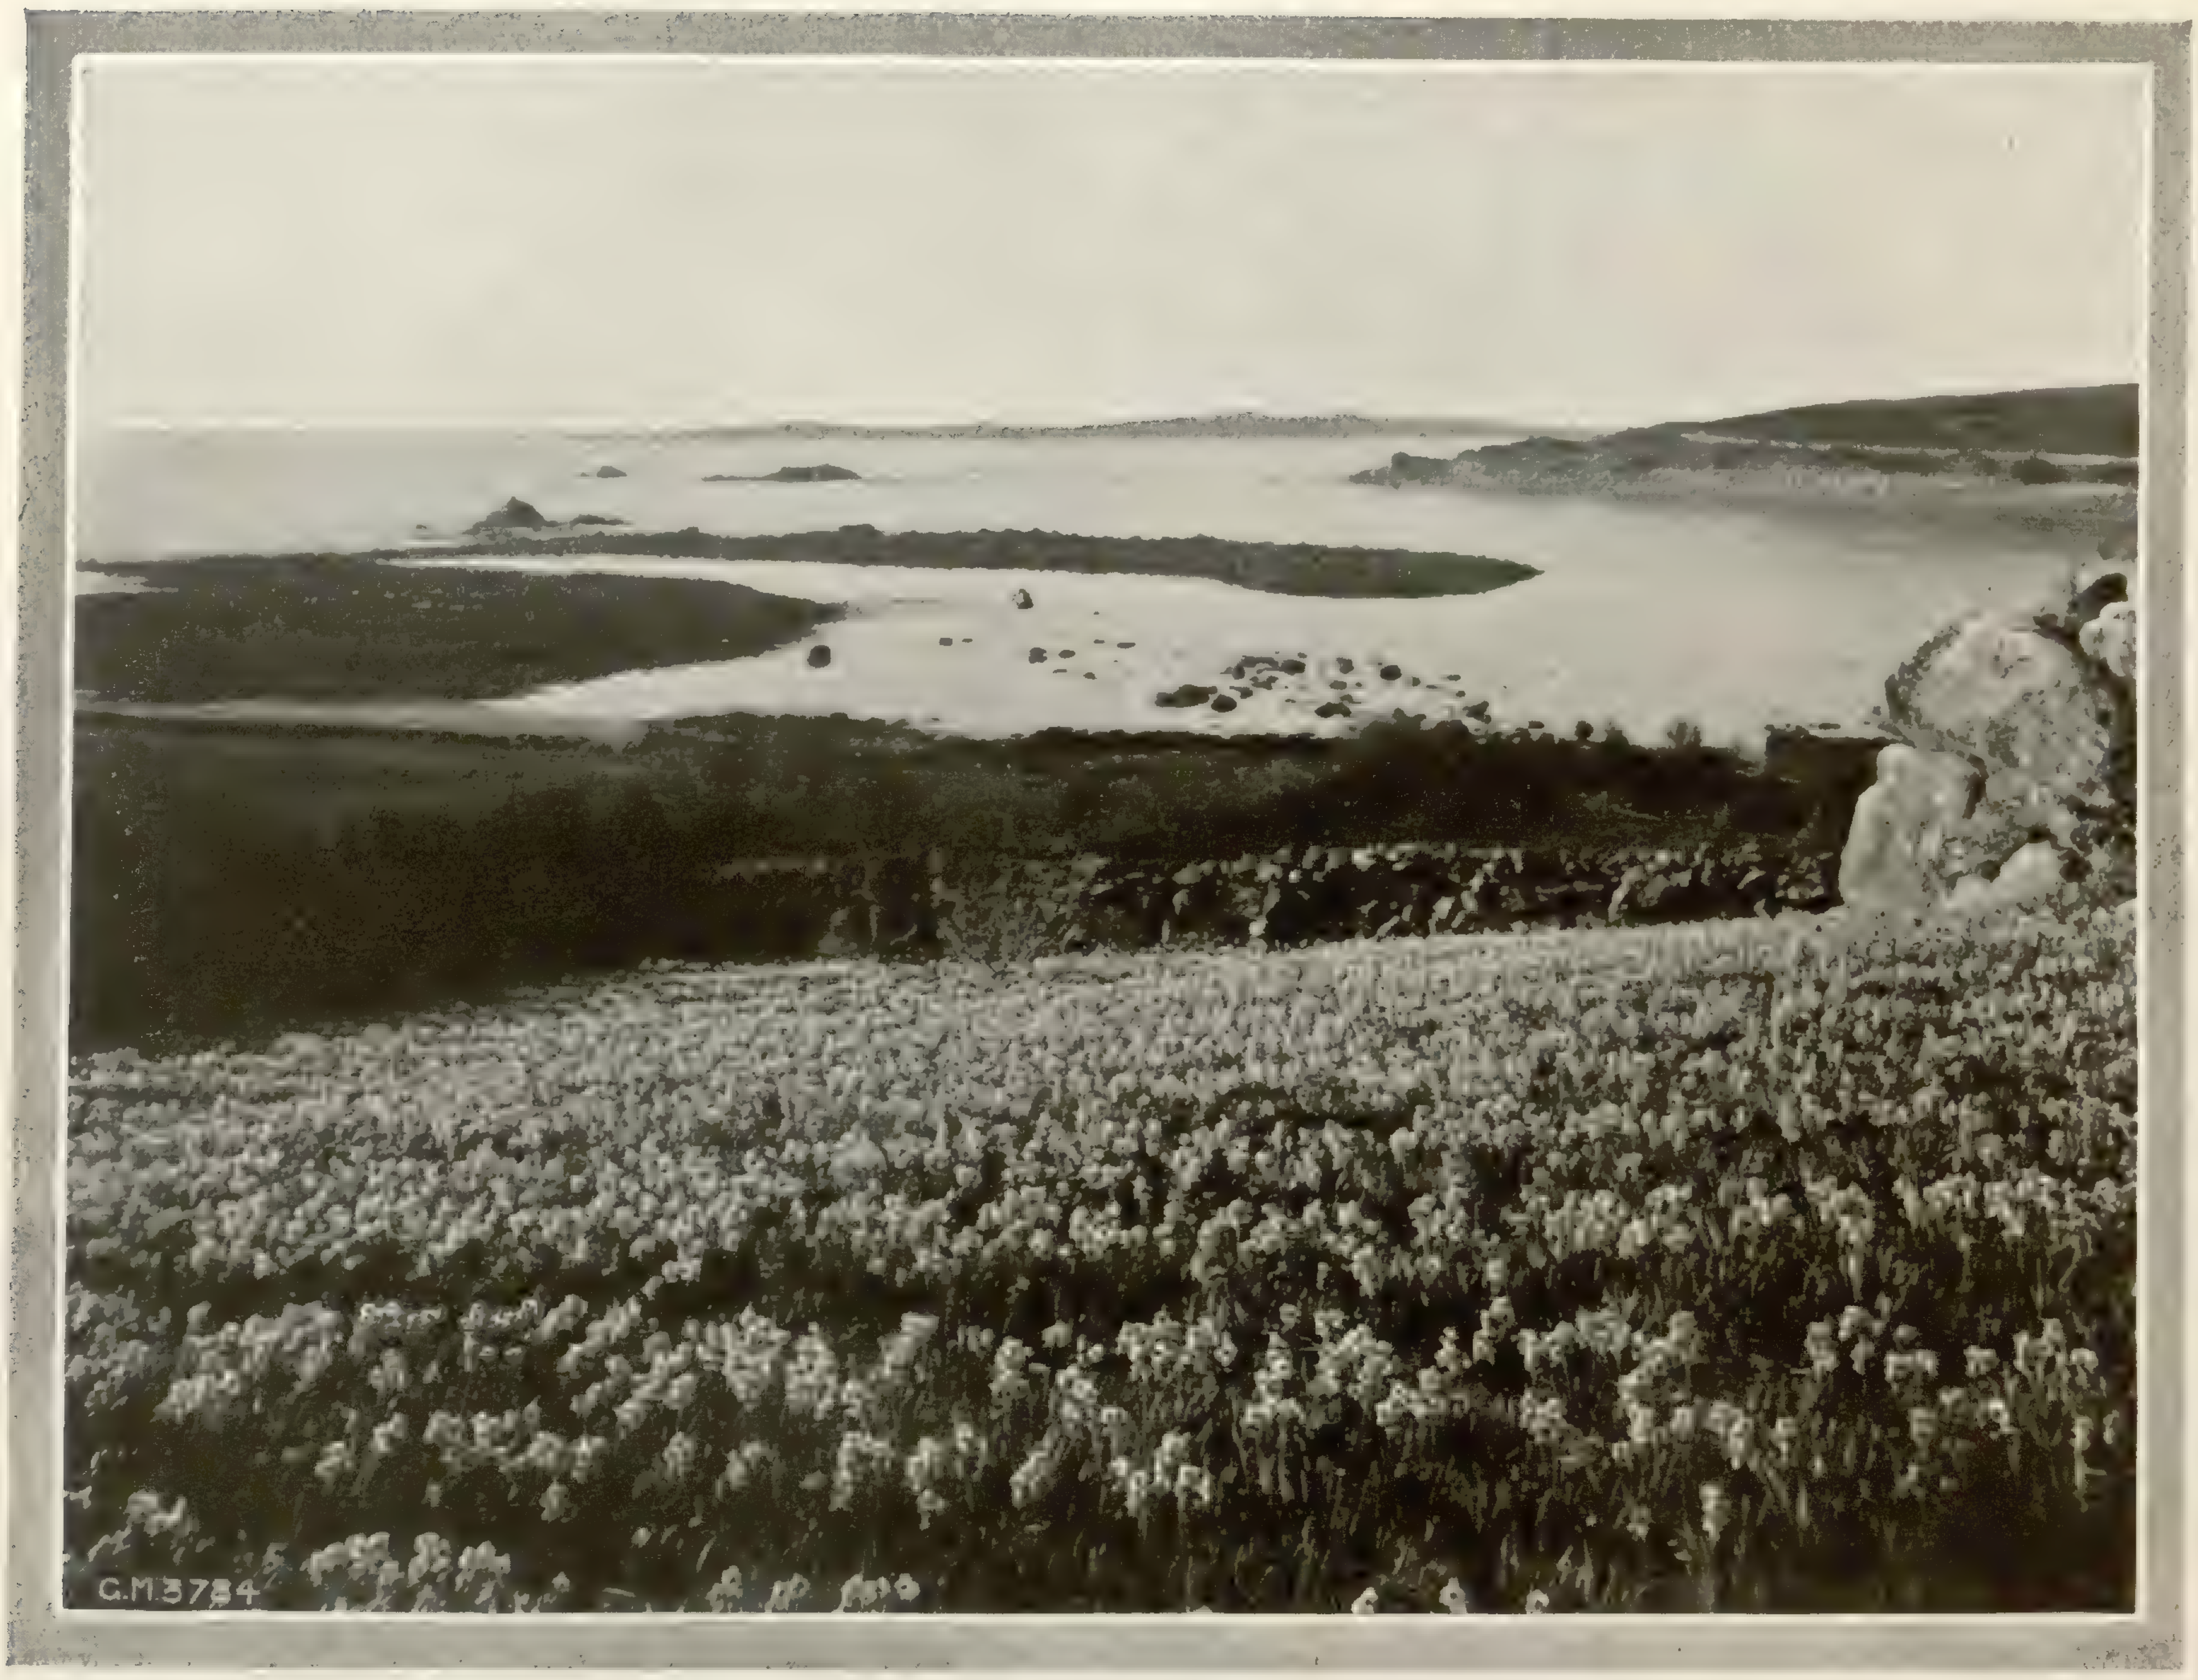
Buxted Park. H. C. Prinsep.

ASTER GRANDIFLORUS.

The average gardener finds the Christmas Daisy—Aster grandiflorus—a disappointing plant indeed, not on account of cultural disability, because there is none of this, out on account of its very late-flowering season. In the East of England, and in other cold districts, the plants have very little chance of developing more than a few terminal flowers. The tufts of subsidiary ones are literally nipped in the bud, and cannot expand. Those who value the plant and have plenty of glass accommodation find it an easy matter to lift the clumps as they develop flower buds, pot them, and gently bring them into flower with the chrysanthemums. I have seen many clumps so treated in Scottish gardens, and they provide many sheaves of lovely violet-blue flowers at a time when this colour in flowers is almost unobtainable, moreover the pot specimens are worthy of the room they require, and are much appreciated when the last aster outside has been destroyed by frosts.

To many gardeners, another way of helping this plant may prove worth a trial, and that is to hasten growth in spring. This aster is a veritable sluggard in growth, wasting six weeks or more if the soil happens to be wet and cold in early spring. If cuttings are taken in February, rooted in heat and grown on for a few weeks, finally hardened off in a frame and planted out with six to twelve inches of growth already made, they will flower late in October, and every bud that has strength will flower. Cuttings or rooted pieces will make typical pyramidal bushes in one season. The mode of culture being that considered good for early-flowering chrysanthemums.

G. B. Mallett.



ISLES OF SCILLY: A SEA-GIRT FLOWER FARM AT ST. MARY'S.

THE ISLES OF SCILLY.

The Bulb Industry.

In a previous article enough has been written to show that the Scillonians start with great natural advantages when they set out to grow early flowers for the London and other markets. Clear light, abundant sunshine, and pure air go a long way towards success in flower culture, as these give intensity and purity of colouring, and add substance to the blooms. But in addition to these free and priceless boons, there is the one of temperature, and it also is one that costs the islanders nothing, because the Gulf Stream looks after that part of the business.

The mean temperature in the Isles of Scilly, for November, ranges from 47.6 degrees to 50.8 degrees; for December, from 44.5 degrees to 50.6 degrees; for January, from 45.7 degrees to 47.4 degrees; for February, from 44.2 degrees to 48.1 degrees. These figures show the range from 1900 to 1905. For the same months of the year there may be as many as 105.5, 57.0, 76.3, and 102.7 hours of bright sunshine respectively, though in some years the average for these months is not quite so high. These figures, and the fact that March may have a mean temperature of 48.9 degrees, and 129 hours of sunshine; and that April may have a mean temperature of 49.9 degrees, and 194 hours of sunshine, will serve to show how it is that daffodils are blooming out of doors in the Scillies in February, in the sheltered gardens.

The Daffodils.

The great business of the Scillonians is flower culture, and practically everyone, from the Lord Proprietor downward, has an interest in the trade. About forty years ago there were probably not more than eight kinds or varieties of daffodils to be found in the Isles of Scilly, some as wildings, others in gardens. It is possible that the Benedictine monks of the Priory of St. Nicholas, introduced bulbs to Tresco. But the credit of discovering the commercial possibilities of the islands for flower production must be accorded to the late Mr. Augustus Dorrien-Smith, who sought in every way to improve the condition of the islanders. It is said that his first consignment of flowers to Covent garden was rewarded by a cheque for 20s. Some difficulty was experienced at first in securing the interest of the Scillonians in this new industry. But Mr. Dorrien-Smith himself developed an extensive bulb farm at Tresco, and ere long the more enterprising spirits on St. Mary's followed suit. The rest of the islanders holding land or possessing gardens took up the culture, until now the Isle of St. Mary's seems clothed in daffodils in the early spring time, bulbs filling the ground from quite near the seashore up to where the hard rock puts a bar against cultivation. From that first consignment the industry has developed until in the season that began at Christmas, 1906, and ended in April, 1907, nearly 900 tons of flowers, filling about 140,000 boxes, were despatched from the islands.

The earliest flowers are opened under glass, indeed almost all the flowers, even late in the spring, are fully expanded under glass, to ensure clean, clear blooms, but in January the broad light houses, chiefly span-roofed, are heated, and the flowers, culled from the fields as their buds show colour, are set in deep flower pots—made without a drainage hole—in water. Here they expand quickly, and on the central stage or in an adjoining glass-roofed shed they are packed in boxes and despatched to the salesmen. Thousands of bulbs are also forced into bloom in these houses by the larger growers, and they are grown in boxes, pots, or broad pans, so that flower time in the Scillies now lasts from Christmas almost to June.

The work of bunching and packing is carried out very largely by women and girls, and during the busiest season there is a special arrangement with the school authorities, whereby the young people are released from some part of the schooltime, so that they may assist in the ingathering and despatch of the harvest of flowers.

Bulb Farm at Tresco.

Nowhere has the cultivation of daffodil blooms for the early markets been so carefully studied as at Tresco, where, apart from the Abbey Gardens, Mr. T. A. Dorrien-Smith has an extensive bulb farm, and a fine range of sharp-pitched, comparatively narrow, heated, span-roofed houses, built especially for forcing bulbs. What the total output is I do not know, but it is safe to say that when thirty tons or more of flowers are despatched from St. Mary's in one day, a third of the cargo is furnished by the Tresco farm.

There is no room wasted in these houses. The bulbs are planted thickly in boxes, and the boxes are made to fit the benches in the houses, and when all are in position there is only sufficient room along the central path for the worker to move comfortably. At Tresco, as at the other bulb farms and gardens, the earliest daffodils to flower are the Scilly White and Soleil d'Or, and the first of these are ready for the Christmas markets, sometimes earlier.

Emperor and Empress, Horsfieldi, Sir Watkin, the Campernelli jonquil, poeticus, Grand Monarque, Telamonius plenus, Barri conspicuus, Victoria, Gloria Mundi, Golden Spur, Madame de Graaff, obvallaris, Mrs. Langtry, Frank Miles, and Mrs. J. B. M. Camm are some of the varieties grown more or less extensively at Tresco. The proprietor is always on the look-out for new varieties of commercial merit; he invariably attends the big spring shows at Truro and Plymouth, and he is a member of the Royal Horticultural Society's Narcissus Committee. On the occasion of my visit I saw over a hundred flowers of the fine new poeticus variety Horace being bunched for market, and yet this is as yet a high-priced narcissus. This indicates the enterprise with which the work is conducted at Tresco.

ISLES OF SCILLY: FORCING NARCISSUS POETICUS AT TRESCO.

The packing shed is a very big, light structure, as it needs must be to enable from one thousand to over two thousand boxes of flowers to be packed for despatch at one time. Long, broad tanks extend along the glass side of the shed, and on the water are light wooden rafts made of strips of wood crossing each other at right angles, so as to leave spaces a few inches square between the strips. Into these spaces the flowers are placed as they are brought from the fields, and here they open. The structure is heated at will. One end of the shed is partitioned off to form the tying or bunching room, and here the work proceeds merrily. Six young fellows sit at each bench, and facing them are two others. The latter supply the "bunchers" with the flowers from the big pans, and they also cut the ties and put the bunches back into water ready for the packers. Each man keeps three "bunchers" going, and it is remarkable how quickly the work is done by this method. Now and again someone breaks into music, and the whole company joins in the singing or the whistling, but eyes and hands never falter in the work, and as you watch the score or more of men for a few minutes hundreds of bunches are made up and passed on at almost incredible speed.

On the farm the bulbs are mostly grown in small plots, each surrounded by a high, dense hedge of euonymus, escallonia, or veronica. Careful and regular planting is carried out, and the ground is well cultivated. It is rarely that the bulbs occupy the same plot more than three years, usually a much shorter time. Many acres are under bulb culture, and every care is taken to keep the stock up to a high standard, and to add new varieties for the purpose of testing their merits for market use.

After the daffodils are over the glass houses are occupied by tomatoes. Early potatoes are also grown on the farm, near the daffodil houses, in long pits or frames, and they are usually fit to lift in April.

Rocky Hill.

Every Scillonian knows Rocky Hill, and is prepared to enlarge upon its floral treasures, and everyone who stays at St. Mary's should see Mr. Trevellick's garden, which is open to all who are sufficiently interested in flowers and plants to ask for admission.

As St. Mary's is not big enough to lose oneself in, there is no need to say that Rocky Hill is so far from Hugh Town, or Star Castle, or the church, or other landmark. The hill itself is a mass of grey rock, with patches of greenery, but Rocky Hill, that is the garden, is a delightful spot, nestling under the hill, occupying a very sheltered position. It is a patchwork garden, inasmuch as it is cut up into small portions, each with its surrounding hedges, and such hedges! They may be of bamboo, three or four feet through and twelve to fifteen feet high; of Escallonia macrantha, eight feet high and two feet thick, a delightful mass of green foliage and pink flowers; of the broad-leaved evergreen euonymous, varying much in height; of Veronica Andersoni, six feet high, and very dense; or even of the New Zealand flax, roughly cut into shape with a sickle.

Mr. Trevellick was one of the first to enter heartily into the flower industry, and he reaped the full benefit of the good prices that were obtained in those earlier years. Daffodils are still largely grown in these sheltered plots, and several glass houses are used for expanding, bunching, and packing the flowers.

But it is rather to the interesting plants that Mr. Trevellick has brought together than to the bulbs that I propose to draw attention. Approaching the garden from Hugh Town the scene is distinctly un-English. Towering above the dense hedges and windbreaks of bamboo and phormium rise scores of tall dracænas, varying in size and age, but all carrying good heads of their tough leaves. This is the first view, but on entering the garden, by the side of the house, and passing within the shelter of these hedges, one finds roses flowering freely in the first week of April, Fuchsia fulgens aglow with flowers, Acacia Drummondi just coming into flower, and the whole air redolent with the fragrance of the daffodils that carpet the ground everywhere.

There are some fair-sized apples trees at Rocky Hill, and also some plums, and Mr. Trevellick is as proud of these as of any other of his garden treasures. Pittosporums are plentiful, P. Tobira forming big masses that give shelter to plots of arum lilies. In another spot is a great mass of Lomaria magellanica several yards through, with a huge bay tree close by just coming into flower. Here Hedychium coronarium stays out all the winter without harm, and the common Genista fragrans rises fourteen feet high, and is a mass of yellow blossoms. Clianthus puniceus and Pittosporum undulatum flourish near a collection of old ships' heads that remind one of the dangers of these rocky coasts.

A little dell is almost filled with a great patch of Puya chilensis that is scarcely, if anything, behind the Tresco specimen. This is in a very sheltered spot, and near by is a perfect Araucaria excelsa twenty-five feet high; a beautiful Trachycarpus excelsa, finely furnished with its rich green frondage, and rising over twelve feet high; Choisya ternata, making a huge bush; and Eucalyptus globulus, forty feet high. Close by this spot is another, where Dicksonia antarctica rises fifteen feet high, and spreads out its fronds to cover a space at least thirteen feet across, and, underneath it are herbaceous and stellate cinerarias, self-sown, and perfectly happy.

The splendid masses of hydrangeas, the great tree of the lemon-scented verbena (Lippia citriodora), with its stem almost a foot thick, arching over a pathway; the double blue primroses that edge a rose border, and the giant junipers along the highest walk, are more of the many interesting subjects in a garden that is full of surprises.

Holy Vale.

I was disappointed to find Mr. W. P. Mumford away from home when I visited Holy Vale, where he has an extensive bulb farm, and cultivates for flowers and for bulbs also. Mr. Mumford was also one of the pioneers of the flower industry in the Scillies, and he has a number of large glass houses devoted to forcing bulbs, and ample light sheds for opening and packing the blooms.

The flowers are mostly bunched by girls, and I gathered that some of the girls are so nimble fingered that they can set up a thousand bunches per day. Mr. Mumford does not confine his attention wholly to daffodils, but, like not a few other growers, he cultivates arum lilies on the moist and rich soil of the lower lying fields. Big patches of arums, sheltered by stout walls or dense hedges, are to be found in several districts, and they are an interesting feature of the flower industry. A broad plot, such as shown in the illustration, just before gathering commences, is a fine sight, the pure white spathes rising from a mass of ample rich green leafage.

Old Town.

Mr. Watts, of Old Town, is the largest grower of daffodils in St. Mary's, and in the extent of his cultivation he must occupy almost as important a position as Mr. T. A. Dorrien-Smith. Mr. Watts has a very big business, and a well-kept establishment. He finds it impossible to have all his flowers bunched in the big packing shed during the busy season, and so he arranges with several families living near by to bunch, by piece work, and the flowers are conveyed to these homes direct from the fields or the houses, and brought from the homes to the shed to be packed.

Mr. Watts has from fifty to sixty acres of daffodils, and the cleanliness of the beds and the neatness of his sheltering hedges are ample evidence of good cultivation and keen attention to business. Some daffodils must be replanted every two years, some every three years, but some varieties may be left as long as ten years undisturbed, but, as Mr. Watts points out, this is bad practice.

In answer to a question that was suggested by some of the plots of daffodils growing on the smaller bulb gardens I passed through, Mr. Watts expressed the conviction that in some cases bulbs had not been lifted and replanted for upwards of fifteen years. Such plots as these pay poorly, and the flowers from them tend to keep prices down. It would seem that a combination of the growers for the purpose of preventing the export of all blooms below a certain grade would effectually put a check to the careless cultivation, or lack of cultivation, followed chiefly by those who have other interests, and are not wholly dependent upon their flowers.

Mr. Watts has three long span-roofed houses, each 217 feet by 20 feet, in which daffodils are forced for the Christmas and New Year markets. Scilly White and Soleil d'Or are most largely grown for early forcing. Sixteen-sized pots are extensively used, and in these about sixty bulbs are planted as closely together as possible, but when boxes are used a hundred bulbs are put in each. Mr. Watts says that for early forcing all the varieties, except ornatus, may be packed thus closely together.

ISLES OF SCILLY: DRACÆNA GROVE IN MR. TREVELLICK'S GARDEN AT ROCKY HILL.

Twelve flowers are placed in each bunch, arranged so that they all face one way and do not overlap one another materially. It requires from fifty to sixty bunches to fill a box, the boxes being lined with whitey-brown paper, and covered with white or blue paper. Just as some varieties occupy more room than others when bunched, so some are much heavier than others, and it is found that the boxes vary from eight to eleven per hundredweight.

Mr. Watts, and also Mr. Dorrien-Smith, supply flowers in their own boxes, and not in salesmen's boxes, and in every case the name and mark of the sender is prominent. I am not quite sure, but I believe Mr. Watts said he now used light, non-returnable boxes.

Daffodils Everywhere.

The forced daffodils, and also the small bulbs removed during the replanting operations, are frequently thrown into heaps on a piece of open unused ground. By various means they find their way from thence into hedgerows, lane sides, on to the common land, and round among the rocks, so that they are found blooming everywhere. It is safe to say there are daffodils in every garden in St. Mary's. The coastguards' plots are, in some cases, filled with them, and they are to be found in the churchyard and along the fortifications, as well as among the grass near Peninnis Head, not far from the famous Pulpit Rock.

On St. Martin's, and also on St. Agnes' daffodils are grown in lesser quantities, and from here they are brought by sailing boats to St. Mary's to meet the outward-bound steamers. From Tresco the flowers are brought by a steam launch that often has other boatloads in tow. There is much shouting and joking as the boxes are got on board, for visitors, and most of the folks who are not otherwise engaged—and, by the way, folks seem to have a lot of leisure time in the Scillies—gather on the pier to see the "Lyonnesse," or the "Lady of the Isles," start for the mainland. Next morning, when you are buying your daffodil buttonhole in Piccadilly Circus or Cheapside, the Scillonian grower is scanning a telegram that tells of the prices his flowers obtained, and the daffodil you wear so bravely was in the Isles of Scilly twenty-four hours ago, and it has travelled by road, by steamer, and by train not fewer than 370 miles.

You may dine in London in the evening, take the night train for Penzance, and lunch next day in St. Mary's. To horticulturists the Isles of Scilly offer an opportunity for a quiet and vastly interesting holiday, but, as Sir Walter Besant so cleverly puts it, each one "must just walk about, sail about, and look about. If after a week he is not contented, I have no more to say."

CHARLES H. CURTIS.

ISLES OF SCILLY: SHELTERED PLOTS OF ARUM LILIES, IN ST. MARY'S.

Tea Roses in Pots.—A good supply of tea rose buds is always appreciated at Easter and thereabouts, and the way to get them is to introduce a few plants to the greenhouse now. These should be well established in their pots, or forcing may not be quite a success. The plants should be pruned a few days after bringing them indoors, and it is well at the same time to look them over carefully for brown scale; this pest spreads rapidly in heat and moisture, and does much damage. At first the plants should have quite a cool temperature, gradually increasing this as growth proceeds; a vinery starting is an excellent place for pot roses. When syringing the vines see that the roses get their share, for this will greatly assist the buds to start into growth.—E. J. K.

SOME RARE SHRUBS.

◆

Abutilon vitifolium.

This Chilian shrub is a very handsome object when in flower early in June. It is quite hardy in South Devon and Cornwall, where it will attain a height of from fifteen to twenty feet. Large examples, when covered with their flat lavender, or pure white blossoms, are very lovely. It has a habit of dying off suddenly without apparent cause, and in some gardens absolutely refuses to grow. Fine specimens, twelve feet in height and as much through, that appear in perfect health, are one day found with flagging leaves, and in a few weeks are dead. In one Devon garden over fifty good plants were lost last year.

Anopterus glandulosa.

This is a beautiful Tasmanian shrub, and is rarely met with in gardens. Its glossy, deep green serrated leaves are six inches long, and its flowers, which are cup-shaped and about half an inch in diameter, are borne in erect, terminal racemes. In Tresco Abbey gardens, Isles of Scilly, there is a splendid specimen ten feet in height and as much through, which in the early spring is white with blossom. It is a wonderfully free flowerer.

Bowkeria Triphylla.

This is a very rare South African shrub, probably not grown in more than three English gardens. It has sessile, lanceolate leaves, in groups of three, and its porcelain-white flowers resemble those of a calceolaria, and are borne in racemes of six or seven. They measure an inch across and the same from top of the hood to the base of the lip. It is apparently fairly hardy, as a plant here, seven feet in height, was uninjured by 10 degrees of frost on four nights.

Buddleia Colvillei.

This comes from the Sikkim Himalayas, is quite hardy in the south-west. It is a striking sight when every shoot is terminated by a large cluster of rose-coloured flowers. According to my experience it does not bloom until it attains a height of about eight feet. The example here bore numerous seed-pods this year.

Cassia corymbosa.

This shrub is a native of Buenos Ayres, and is largely grown as a wall plant in the south-west. There is a splendid specimen at Tregye, and at Trebah a large portion of the front of the house is covered with it. It comes into bloom in August, when it is a sheet of bright gold, and retains its blossoms for a very lengthened period, generally carrying some until Christmas.

Callistemon salignus.

This is an Australian shrub, also hardy in the south-west. This is the plant sold by nurserymen under the name of Metrosideros floribunda. According to Kew the colour of its flowers is crimson, but in Nicholson's dictionary of horticulture the colour is given as pale yellow. Both are doubtless forms of the same species. At Menabilly there is a fine bush of the straw-coloured variety, about ten feet in height and of like diameter, and there are many fine specimens of the crimson-flowered type in Devon and Cornwall which flower profusely.

Clethra arborea.

A native of Madeira, and is called the lily of the valley tree, from its racemes of white, bell-shaped blossoms resembling that flower. It blooms in August, and is very beautiful when white with blossom. It is grown as a shrub in the open in many gardens in Devon and Cornwall, the finest specimen being probably that at Trewidden, which is fifteen feet in height. There is also a very large one at Tregye. The plant here had its young leaves killed by ten degrees of frost, but was not otherwise damaged.

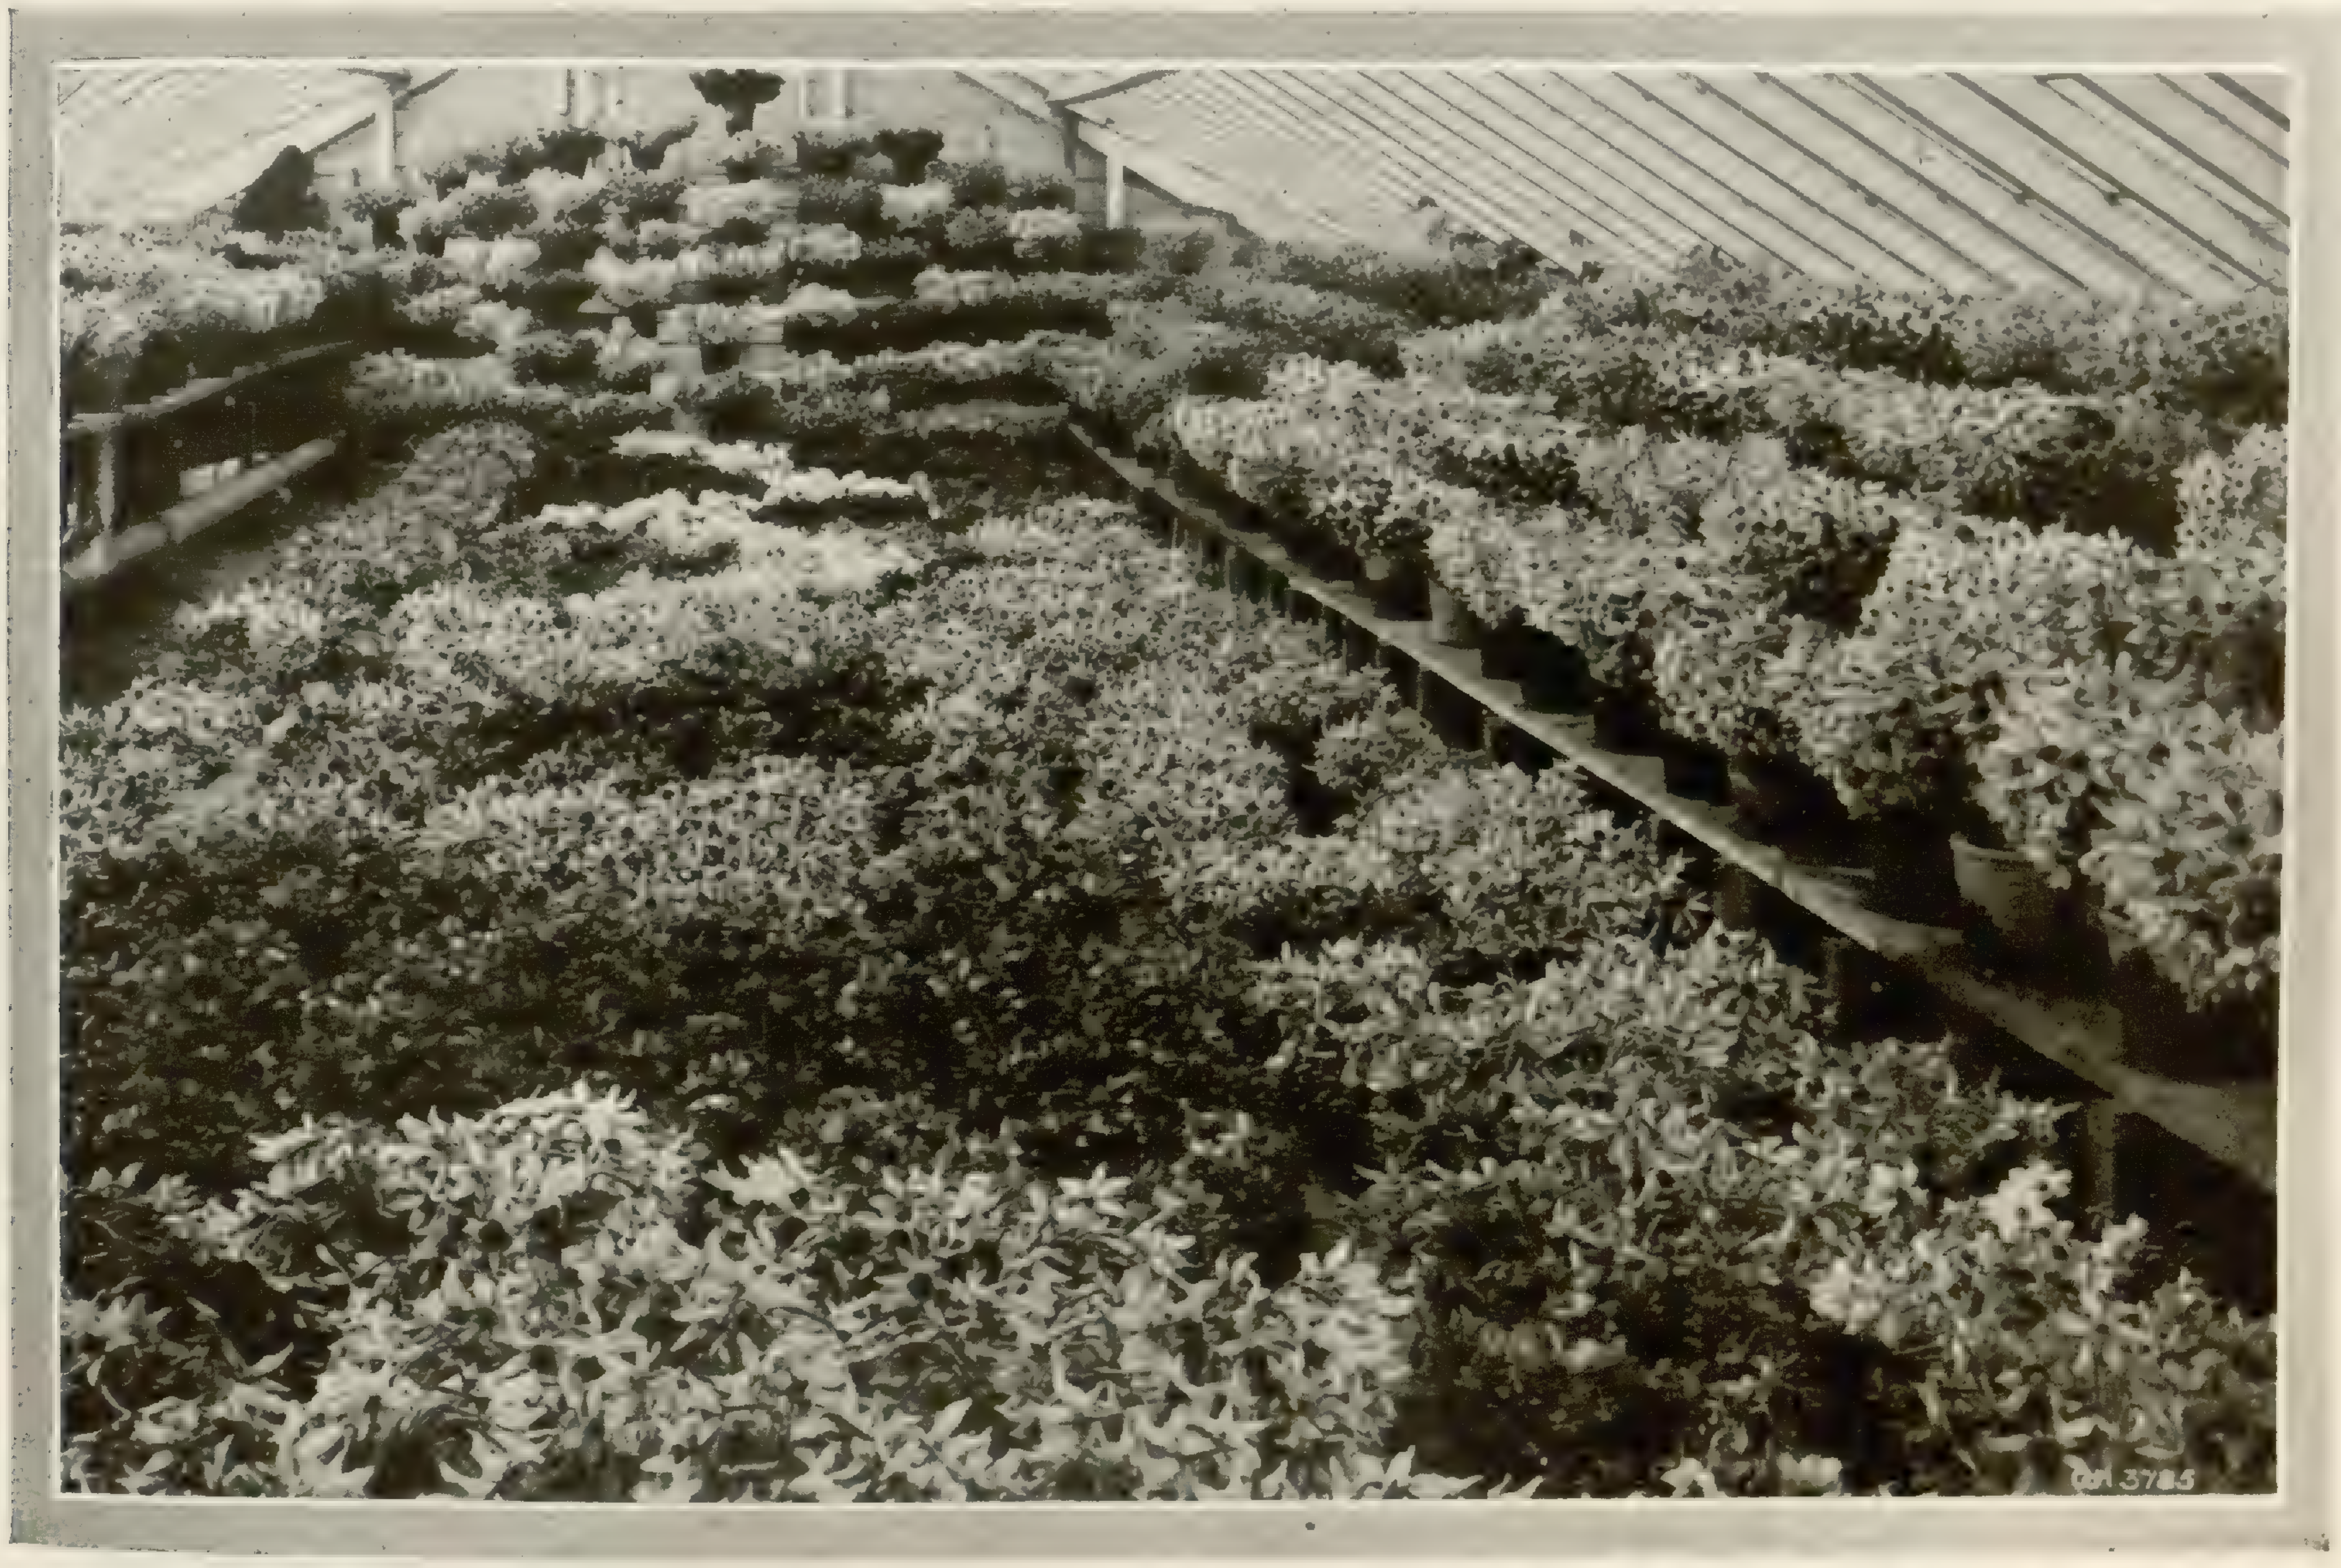
S. W. FITZHERBERT.

Kingswear, South Devon.

CLEANLINESS IN CULTURE.

The number and variety of garden pests, insect, animal, vegetable, and fungoid, is truly alarming; but is it not a fact that cultivators are largely to blame for their undiminished prevalence? Is it not certain rather than doubtful that, although cleanliness of the person is looked on as an essential virtue, yet cleanliness of plants and place is regarded too much as an ideal, and unattainable at that? I fear that despite all protests and excuses it must be said that, in relation to their plants, gardeners do not take the means which are clearly in their power to ensure that degree of cleanliness of plants which is an essential condition to the enjoyment of good health.

Without further attempting to fix the blame I will proceed to point the remedy.



ISLES OF SCILLY: THE "TYING" HOUSE ON MR. WATTS'S BULB FARM AT OLD TOWN.

Under this title I do not intend to treat of measures for the eradication of pests, but rather preventive means. First, as to the kitchen garden. It is well known that deep culture (which does not necessarily mean only trenching and double digging) is a powerful means of keeping the land free of insect pests and weeds. Seeds of weeds, if buried deep, are less likely to germinate, and similarly if the larvæ of many pests are put well below the surface there is at least a strong probability that many of them will fail again to reach the zone wherein they become dangerous to crops. A soil also well charged with lime, and one enriched with manure (which can be traced to its source to prevent contact with seeds of hay and other obnoxious weeds), will exhibit a cleaner surface than one where such simple precautions are not considered.

Then again weeds are often allowed to go to seed either in the beds or on the walks, which, if the exigences of time did not admit of their being hoed up or otherwise destroyed, could at least be mown down before the seed had formed. Timely work with the hoe will, of course, do much to lessen the prevalence of weeds, and we know that weeds are often guilty of harbouring many pests. In gardens which are bounded by hedges it is common to be told that it is impossible to keep down weeds and pests with a hedge for a boundary, and that there is nothing better than a good wall. While agreeing with the latter opinion, it must be recognised that hedges, as a source of weeds and pests, can be largely nullified by keeping the hedge bottom clean, a work that is well nigh universally neglected. It is but reasonable to suppose that the hedge bottom will harbour more pests when choked with weeds and rubbish than when kept clean.

Too often insufficient care is taken in the removal of couch grass and other troublesome weeds, as well as the vegetable remains of diseased plants. It does not necessitate more work to simply put these in a heap and make a fire of them than to take them to the rubbish yard; and there is no question of alternative as a matter of safety. Many gardeners still use the same site for their seed beds every year. Now I am fully convinced that this is a prolific cause of the prevalence of disease. I remember on one occasion advising a change of seed beds to a gardener who was annually troubled with club-root, and he acted on that advice, with excellent results. To puddle the roots of plants of the cabbage family in a mixture of clay, soot, and lime and water before planting is a means of prevention which necessitates but a few extra moments of work, and may be the saving of much disappointment. To wash and point a brick wall where young trees are to be planted is a work upon which too little value is set.

In the glass department the doctrine of hot water needs to be persistently advocated. The plentiful use of hot, and, when possible, boiling water when washing a house will greatly reduce the need for insecticides. Boiling water will destroy almost all living things, and when the house is empty, as it should be for cleaning, there should be no stint in its use. For woodwork, glass, floor, pipes, shingle, walls, etc., it should be freely used. Paraffin is a cheap and powerful insecticide, which can be largely used for washing out purposes when the house is clear of plants. When a house that has been thoroughly washed, it is a good plan to examine the whole of the inside with a tin of paraffin and an old paint brush, and work this powerful pest destroyer into all holes, corners, cracks, and interstices from top to bottom.

It should be made a practice, whenever possible, to wash both the outside and the inside of the house at the same time, so that from the apex of the roof to the footings of the foundations all parts of the structure will have been brought within the purifying influence of soap and water. Hot soapy water is also good for syringing infested creepers, if done regularly twice a week. In the interests of cleanliness it will often be necessary to consider the advisability of destroying the creepers entirely, for once they become infested with bug it is well nigh impossible to thoroughly clean them or to keep clean the plants beneath them.

The remarks above relating to the destruction by fire of all infested and diseased plants applies to the glass department as well as to the kitchen garden. Spraying, dipping, and other remedial measures will prove abortive if the simple means of prevention which must occur to any thinking man be not carried out. How simple a matter it is to destroy all infested plants, either collectively in a smother fire, or individually in the boiler furnace, instead of throwing them beneath the potting bench, or allowing their remains to fall about on the greenhouse floor. Especially does this apply in the case of an attack of chrysanthemum rust or other fungoid diseases, which are so easily spread and so difficult to check.

If other similarly easy means of combating our enemies were taken advantage of there would be less trouble everywhere. For instance, cuttings of suspected plants or from a suspicious source, should be dipped. All plants, cuttings, bulbs, etc., from places where pests are known to abound should be kept in quarantine until their immunity from disease, etc., is fully established. Above all, the propagating frame should be clean, and in every way above suspicion. The material should be frequently changed.

Finally, let it be remembered that dirty pots, boxes, floors, walls, shingle, etc., as well as a want of care in stacking turf, leaves, and manure, are means whereby disease and pests are spread, the work of combating them increased, and the health of the plants jeopardised.

W. F. Rowles.

CHRYSANTHEMUMS IN BASKETS.

The illustration you gave on page 803 of last year's volume, should influence those who have not seen such exhibits to imitate them, either as a class at the autumn shows or arranged for their private use. Tastefully arranged in baskets of any size or shape chrysanthemum blooms, large or small, lend themselves to this form of decoration admirably. I think societies who have not a class of this kind in their prize list lose a beautiful feature at their shows. Not only does such a class provide much interest, but it affords an object-lesson of much value to those who arrange flowers for home decoration.

Any form of basket can be fitted with a vase or receptacle of a suitable kind, even a jam pot will suffice; something that is not too cumbersome that will contain water in which blossoms can be arranged for the drawing-room or hall is all that is necessary. Such a class affords an opportunity of utilising the many kinds of autumn foliage and berries in conjunction with chrysanthemums. For instance, the foliage of scarlet and dark coloured oaks, Prunus Pissardi, Guelder rose, spireas, and so forth all may be utilised in making a telling display when arranged in conjunction with the blooms of the chrysanthemums.

Ten years since the committee of the Windsor Chrysanthemum Society at their autumn show had a class for twelve Japanese blooms arranged with any sort of cut foliage. This was a class that was distinctly popular, as a dozen exhibitors took part in the competition; the result was an admirable object-lesson of how to utilise large Japanese blooms for decoration. In a basket more so than in a vase, perhaps, large blooms can be most advantageously employed, as a greater area is provided, and it is more easy to arrange the blooms without undue crowding.

At York baskets of chrysanthemums are encouraged with their own foliage. In many instances there, Source d'Or and its yellow sport are employed, and with splendid success.

In no other way can a better effect be produced, especially by single-flowered varieties, than by arranging them in baskets. In arranging the flowers the greatest mistake made is that of overcrowding them, every bloom should stand clear of its neighbour, except in the case of undisbudded sprays.

E. Molyneux.

FERN SPORES.

Among cryptogamic plants it is certainly in the ferns that the faculty of reproduction by microscopic spores strikes the observer most, because in them we find the development of the foliage to approach more nearly to that of flowering plants proper, both in make and dimensions.

In no other tribe of cryptogamic or spore-bearing plants, with the exception perhaps of some of the gigantic seaweeds, can we find anything to rival in height and spread of foliage a good-sized palm tree as does a well-developed tree fern, such as a Dicksonia, alsophila, or cyathea. In the familiar plant world we are apt to expect the size of the seed to bear some relation to that of the adult plant, but comparing the initial stage of a huge tree fern and that, say, of a cocoanut palm of similar size, we find, in the first case, that the spore is so small that the unaided eye cannot detect it, while in the second case the new generation starts with a fruit possibly a foot long in its enveloping husk and shell. The one reproductive body indeed is many million times smaller than the other, and is yet capable of producing an equally large specimen.

In view of this capacity, the tree fern would apparently possess an immense advantage over the cocoanut palm, when we consider that its annual crop of spores is, numerically, inconceivably great, many thousands of millions covering the entire under surfaces of the huge fronds of a healthily fertile specimen. It is obvious, however, that the numerical advantage is fully handicapped by the minuteness of the individual spore, since the practical capacity of holding its own is no greater in the fern than in the cocoanut, the vast bulk of spores perishing.

This is owing to the fact that the process of producing the fern from the spore is a delicate one, necessitating non-disturbance and humid conditions, and that at the critical period of fertilisation the necessary apparatus is still very minute, consisting of a tiny green scale only a quarter of an inch across, or even less. The little scale which is the first product of the germinating spore, becomes attached to the soil by a multitude of fine roothairs, and on its underside two sets of bodies are produced which are practically male and female flowers, each of the latter having what, to all intents and purposes, is an embryo seed embedded at its base. This seed, being fertilised by means of swimming antherozoids, the equivalent of pollen grains, produces a tiny frondlet with a bud at its base and a root which penetrates the soil, and the fern is launched into existence. Up to this point it has been a delicate little affair, liable to be dislodged or devoured by a myriad insects or washed away by the merest shower, or, worse still, the spore, when shed, may have lodged on other vegetation, or, under other circumstances which gave it no chance of germinating at all.

That the numerical loss is not due to lack of reproductive power in the spores themselves is shown by the fact that if we sow a very minute portion of the crop, a tiny heap scarcely perceptible to the eye, on properly sterilised soil and under favourable conditions of growth, a considerable number of young ferns will, as a rule, result, proving that most, if not all of the spores are fully capable of germinating, and reproducing a new generation if they have the chance.

Every genus of fern bears its spores in its own particular fashion, since it is mainly on the basis of such arrangement that botanists have classified ferns. Roughly, they may be divided into three classes, viz., those which bear their spores on the backs of the fronds, on the edges of the fronds, and on altogether specialised fronds or portions of fronds. We may typify these by the common Polypody (Polypodium vulgare), which has round golden heaps of spore capsules on the undersides of its fronds; the well-known Haresfoot Fern (Davallia canariense), which carries its spores in marginal pockets, and the Royal Fern (Osmunda regalis), which has the tips of its fronds contracted into panicles consisting of bunches of spore capsules, giving it a false appearance of inflorescence, whence its name of flowering fern.

All three categories, however, show great multiformity in detail, the arrangements at the backs of the frond being in dots, lines along the margin and within it, or broken up into short segments, as we see respectively in the polypody cited, in which the round heaps are uncovered, and in the Male and Shield Ferns (Lastreas and Polystichums), in which they are protected by a sort of skin (indusium), in the common Bracken (Pteris aquilina), where the spore heaps lie in even lines along, but underneath the margin; in the Spleenwort (Asplenia) and the Hartstongue (Scolopendrium vulgare), in both of which they lie in lines along internal veins arranged herring-bone fashion, and finally in the Maidenhair Ferns (Adiantum), in which they form short marginal heaps.

If, therefore, we familiarise ourselves with the typical generic arrangement, it matters little how the fronds may differ in character in the numerous species or varieties, they betray their relationship at once if they be fertile. The spore capsules in the great majority of cases are of a lucent brown tint, oval in shape, and attached by a stalk, which is continued from its point of attachment up and over the top and halfway down the other side as a ribbed projection, which, when the spores are ripe, contracts so strongly that the capsule is ruptured at the point where the rib terminates, and is torn violently and suddenly open, the upper portion flying backwards, and with the shock scattering the spores far and wide.

In a few species the ring, or rib, is either absent or runs round the upper portion horizontally, and in still fewer the spores are contained in different receptacles altogether, termed synangia. The spores in most species are brown, some smooth and oval, and others roundish and ridged; in the Royal Fern (Osmunda regalis), however, they are a light olive green, even when ripe, and in the common polypody they are bright orange-yellow, as are the capsules themselves. In speaking above of the capacity for germination we used the expression "as a rule" as regards abundant offspring, since fern spores vary considerably in their readiness to germinate, some becoming veritable weeds, while others germinate very slowly and are difficult to raise from despite every care. In many cases this slowness appears to be correlated with extra fertility in other directions, in the way of bulbil plants on the fronds numerous offsets, or travelling rootstocks, all of which tend to propagate the fern freely. Nature having in this, as in other cases, furnished increased means of propagation in one direction, reduces them in another by way of compensation.

Chas. T. Druery, V.M.H., F.L.S.

THE POSITION OF GARDENERS.

Allow me to thank "A. G. B." for his very complimentary reference to my article on the position of gardeners, which appeared in these pages on November 9, 1907. The question is a very knotty one, but I must confess I fail to see a solution of it just at present. "A. G. B." objects to men calling themselves gardeners who have no more right to do this than a house-painter has to style himself an artist. Just so, but when does a man cease to be a labourer or general factotum and begin to be a gardener. At present there is no line of distinction, nor is there likely to be while one hears people who employ a man to do the pony, cow, pigs, knives, boots, windows, etc., proudly referring to him as "the gardener." I am afraid there is no possibility of an Act of Parliament to stop people who employ a general odd man calling him a gardener, and if the latter gets the title from his master or mistress you cannot blame him for using it himself.

"A. G. B." considers that no man should be permitted to practise as a gardener unless he has passed an examination, and holds a certificate to show that he is proficient. There would certainly be something in this if, after obtaining his certificate, the gardener could command a respectable salary on the strength of it, but in most cases employers pay their gardeners what they can afford rather than what the latter are worth, and a stipend of a pound or twenty-five shillings a week would not be a big reward for passing an examination. Further, what kind of an examination would "A. G. B." suggest? We already have examinations in horticulture, and I notice that the certificates are chiefly won by college students—mostly girls, by the way. If "A. G. B." were an employer and owner of a garden, I wonder if he would like to put it in charge of one of these students, on the strength of the fact that he or she holds a certificate.

I am afraid the kind of examination that would act as a safe test of the ability of a gardener has yet to be devised, and I would rather favour a system of apprenticeship, by which a man could show that he had had so many years' training in a suitable establishment, and had the right in consequence to call himself a gardener. What I object to is the present wholesale system of making gardeners. Take the average establishment, where there is one head gardener and three or four young men in the bothy. What does it amount to? Three or four men are being trained to compete for one man's place, and they can't all have it. The result is that some must drop out or content themselves with the single-handed berths, where a host of odd jobs are mixed up with the horticulture.

Gardeners have, in my opinion, had a big finger in the pie that has led to the present state of over-crowding, and the lowering of the position of the profession in the eyes of the world. Gardeners have largely been the means of increasing the bothy system, by which labourers are done away with and gardeners in training are employed to do labourer's work. And in the selection of lads to put into bothies and train as gardeners, not half enough care is taken, with the result that the idea has got abroad that anybody will do for a gardener. The old apprenticeship system was in many ways better than the present method, if such it can be called, for, though the gardener of the old school was a bit of an autocrat, he was particular about his pupils, and if they were any good he could generally put them into the way that finally led to a fairly good position. Young gardeners to-day are more of the butterfly order. They flit about from place to place until they wish to get married, and then they have to hunt round to find a way of making a living.

By the way, are employers of gardeners anxious that the standard of men should be raised? I only ask the question because I have never heard any expression of opinion on this point, and it is a matter of some interest. In some cases, now, I am afraid that when engaging gardeners there is a haunting fear amongst a certain class of employer that the man may be too superior for the place. "Oh, I only want a plain kind of gardener, a man who can work and will take orders, but does not profess to know too much." This is the kind of thing one hears sometimes in connection with the engagement of a new gardener. Personally I think a few years at Kew is a splendid training for a young gardener, because it has somewhat the same effect on him as the finishing touches of a secondary school have on a lad who has been grounded in an elementary school; but I am not sure that all employers think so, because some seem inclined to the opinion that Kew training unfits a man for private service. I should like to hear the views of others on this point.

Gardeners are supposed to be badly paid in England, but here salaries are lucrative compared to what they are in Ireland, according to the testimony of an Irish member of the B.G.A., who has made a collection of advertisements culled from various papers in the Green Isle. I learn from a few selections taken from the bulk that the magnificent stipend of 12s. a week, with a free house, is offered for a gardener who is married and thoroughly understands his business. Aspirants to headships, please do not all speak at once, as the place may be filled. Thirteen shillings a week is offered for another gardener, but for this he must understand glass, and his wife must attend gate. The perquisites are summed up in two words—milk, lodge. With these examples it would be well to stop for fear we get worse, but if Irish gardeners should emigrate in a body by way of protest, who can blame them?

I notice that an interesting question was put at a recent meeting of the Bristol Gardeners' Association, viz., "Can anything be done to stop book travellers pestering young men for orders?" There is something original about this, and I should like to hear whether any satisfactory solution was given to the problem. Most of us know something of the gardening book canvasser, and if some authors of horticultural works were aware of the way he talks young gardeners into giving orders they would never write another book on horticulture. I can see him now, the typical book canvasser, a man of shabby genteel appearance, but with a tongue as near approaching perpetual motion as it is possible to get. He has talked and talked and talked to a lad earning 12s. a week until he has persuaded the latter that his professional existence depends on having a dictionary or something that will absorb one or two shillings a week out of the modest twelve, and, having achieved this victory, he goes to pitch the same yarn into some other unoffending journeyman. One wonders that men with such powers of tenacity and persuasion have not achieved something greater.

SPY.

Forcing Mint and Tarragon.—To pick useful green sprigs of mint and tarragon early in the year demands not so much skill as the exercise of a little forethought. I have known excellent and long sustained pickings to be obtained by simply running a spade under a few roots in the bed and transferring them to the inside border of a peach house, where they shared in the syringing given to the trees. A variant of this system is to place the roots in shallow boxes, and then stand them about the vinery or peach house. This is the better plan, as the boxes can be moved to a cold frame if necessary.—E. J. K.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

DECIDUOUS CALANTHES.—The numerous species and hybrids belonging to this winter-flowering genus will now be passing out of bloom. As soon as the flower scapes have been removed the potting compost should be allowed to become quite dry; when the grower is satisfied that the compost is free from moisture, the pots containing the pseudo-bulbs should be placed on a shelf or some other suitable position, where they may obtain the full advantage of available light. Where a large number of calanthes are grown, the storage of the pseudo-bulbs in their pots, as above mentioned, takes up much space, and this, where room is limited, is often a matter of consideration. In such cases it is a good plan to turn the pseudo-bulbs out of the pots, shake away all the old compost, and cut away the roots to within about an inch of the base of the last-made pseudo-bulb. The old bulbs should also be severed from the new ones at this time. Care must be observed to carefully label both the old and new bulbs when turning them out of the pots to avoid mistakes hereafter. When all the plants have been turned out of their pots, and the dead and decaying matter has been removed, take care to see that there is no scale lurking at the extreme base of the bulbs.

STORAGE OF PSEUDO-BULBS.—Select some shallow boxes, such as are used for ordinary propagating purposes, and at the bottom of the boxes place a layer, about one inch deep, of clean dried chopped sphagnum moss, freely intermixed with coarse silver sand or finely-broken crocks. On this layer the pseudo-bulbs may be stood, close together in an upright position, taking care that each kind is separated by a lath and properly labelled. The old bulbs should be given a box to themselves, as these are useful in cases where it is desirable to increase the stock. The boxes may then be stood close together in a suitable position, and space will be considerably minimised, compared with the room occupied, when they are stored in their pots. We adopt this method and leave the plants in the boxes until the growth becomes sufficiently advanced to repot in spring, the necessary encouragement being given after growth commences by keeping the moss moist at the bottom of the boxes. Some of the calanthes of the C. Regnieri section, which are late-flowering, must be kept moist at the roots and in a genial atmosphere until after the flower-scapes have been removed, after which they may be treated as above advised.

ORCHIDS COMING INTO FLOWER should be placed in a position where they may have full advantage of the light at the present season. One can scarcely realise the difference that light has upon plants. If we take, for example, a fine coloured form of Odontoglossum crispum flowering at the present season, and compare its flowers with those of the same variety expanded in the months of April and May, or any of the brighter months of the year, the lack of colour pigment will be found very great. Not only is there a deficiency in the colour of flowers produced in the winter, but the texture is also unsatisfactory. This may be to some extent remedied by the cultivator taking advantage of every facility for placing the plants under favourable conditions. In cases where the plants are at a distance from the roof glass, there will be a tendency in advancing spikes and flower-scapes to become drawn and weakly. By placing such within reasonable distance of the glass, these undesirable conditions may be minimised.—H. J. CHAPMAN, Oakwood, Wylam-on-Tyne.

CONSERVATORY AND GREENHOUSE.

GENERAL MANAGEMENT.—Throughout this month plants in the conservatory and greenhouse should not be stimulated by heat, and although some of them will bear a temperature nearly as low as the freezing point for a short time, without being apparently injured, yet such must be considered an exception to that which is natural to their constitution, and therefore the temperature should not be allowed to fall below 40 degrees, unless in very severe weather, when that point can only be maintained by so much fire heat as would render the air of the house too dry. Amongst plants usually introduced to the conservatory will be found some that require a considerably higher temperature than others, and on this account it will be advisable to maintain a temperature ranging from 40 to 45 degrees at night, and 50 degrees by day, or 55 degrees with sun heat and plenty of air. It it should be too damp although sufficiently mild, fire heat should be given to raise the internal temperature two or three degrees throughout the day, above that of the external air. Water sparingly, but effectually, when the soil in the pots indicates the desirability of watering.

GYPSOPHILA ELEGANS.—This is a most useful subject when grown in pots for the conservatory or house decoration. It is also very useful in a cut state, and can be had in bloom nearly every month of the year by a succession of sowings. Seed may now be sown thinly in five-inch pots, using a light porous compost. Thin out the seedlings, leaving five or six in a pot, and always keep them in a light, cool position. Stake and train as necessary.

CHRYSANTHEMUMS.—Close attention must be paid to the cuttings now in course of propagation. Some varieties root more freely than others. These should be removed immediately they begin to make young growth into another frame, which can be ventilated much more freely, and after a few days the lights may be removed altogether. It is most important that the young growth at this stage, and, indeed, at any other, is strong and short jointed. Coddling should be guarded against at all times; abundance of air must be afforded the cuttings immediately they are sufficiently rooted, but at the same time it is equally bad to rush from one extreme to the other, and the cultivator must be guided to a great extent by the weather and the temperature in which the plants are placed. Always remember that light and air, when chrysanthemums are under glass, will play a most important part as to the final result.

CINERARIAS.—These should have a free circulation of air about them when the weather is mild, and choose the early part of the day for watering. Do not allow the plants to become dry at the roots, and give frequent applications of liquid manure to those developing their buds until the flowers show colour, when it should be discontinued. Plants growing in lean-to houses should be turned regularly to prevent them growing one-sided. Fire heat should only be applied to keep out frost. Keep a sharp look-out for aphis, to the attacks of which cinerarias are especially liable.—T. B. Field, Ashwellthorpe Hall Gardens, Norwich.

THE FLOWER GARDEN.

INTRODUCTORY. — Readers will, of course, readily understand the advice given must to some extent be general rather than particular for a paper having the wide circulation of the Gardeners' Magazine, and due allowance in the matter of time must be made for performing the various operations. At the time of writing this we are having a spell of cold easterly winds with frost, which are to some extent hindering the work outside, though enabling other work to be pressed on. While the ground is clear of snow, leaves not yet raked up, especially on grass near trees where bulbs are planted, should be collected and cleared off, so that when the flowers open there will be nothing to injure them or detract from the effect. As growths are in some cases appearing above ground, care is necessary to avoid damaging them. In warm, sheltered spots the earliest of the snowdrops will soon begin to open, closely followed by the aconite, and where these are planted together at the fringe of or under trees or shrubs in suitable places they make a pleasing combination.

PLANTING.—It is not desirable to do much in the way of planting this month, February being more suitable. If the weather is favourable, and plants are in readiness or waiting to be planted, they may be dealt with. Deciduous and evergreen shrubs may be planted, as also herbaceous plants and late anemones. Sometimes late bought bulbs are planted at this season, but it is not a desirable practice, the bulbs have naturally lost some of their vitality, and have not sufficient length of time to properly root and establish themselves before the flowering season.

ALTERATIONS. — Push on with any ground work, consequent on alterations now in hand, making or turning of walks and general cleaning up, as work will soon come on with a rush. It is best to leave dead fronds on hardy ferns for a time longer, as they are such good protection to the crowns.

PERGOLAS are justly increasing in popularity, and in suitable positions are very beautiful. In their construction avoid making them too narrow, and be careful to have them substantial. Structures of wood, brick, or stone, or of a combination of all these materials, are much better than are those of iron. If wood, the posts should be not less than six inches in diameter, but if thicker, so much the better, as they will then last several years. Materials that are quite permanent, as brick and stone, are preferable. The height, etc., must be decided by the position the pergola is to occupy, it should, however, not be less than eight feet high, and as much wide, while it may be as much as fifteen or sixteen feet wide. Where it is not possible to build a pergola, it is often possible to build one or a series of arches along walks, and at bends or corners, on which roses or other suitable climbing plants may be trained.

AMERICAN ALLSPICE (Chimonanthus fragrans) will now be opening its fragrant flowers, and these may be gathered, laid in shallow saucers of water, and placed in the residence, where their sweet perfume will be much appreciated.

CARNATIONS AND SPRING BEDDERS should have the soil kept firm about them, as generally after frost they are quite loose and cannot root properly. Manure and dig or trench any vacant beds or borders, though with the numerous varieties of plants and shrubs now at command, vacant ground should be very scarce in the flower garden. If weather becomes very severe the most tender things should be protected, either by bracken being lightly secured over beds, mats laid on sticks over them, or similar protection given. Where there are a number of suitable chrysanthemum cuttings on old plants outside, these may be taken and rooted, and the old stools should be lifted, divided, boxed up, and put into an unheated frame or house, as probably, if left in the ground throughout winter, severe frost will kill them.

SNOW AND EVERGREENS. — Should heavy falls of snow occur at once, relieve all evergreen shrubs and trees of the heavy covering to prevent damage or breaking.—E. F. Hazelton, Knowsley Gardens, Prescot.

HARDY FRUITS.

MORELLO CHERRIES.—These, if not already finished and put right for the time being, should be taken in hand at once. The pruning and nailing of Morello cherries I usually commence very early, when the weather is warmer and more suitable for getting on with the work. Before commencing to prune and nail the trees cover the border with some strawy litter, or use planks to tread upon, as this not only prevents the border from being trodden into a sticky state, but is much more comfortable to the worker. Trees which may have been neglected, and require a large amount of thinning, should be removed from the wall and all the old nails, shreds, and ties should be destroyed. Cut out all the old long branches that can well be spared, and retain as much as possible of the young fruiting shoots, not forgetting it is from the young wood as well as the spurs that the cherries are produced. If anything has to be done to the wall it should be done before replacing the branches. Syringing with a mixture of soft soap and paraffin, at a reasonable strength, one small 60-sized flower pot full of paraffin to three gallons of water, together with four ounces of soft soap, is a good practice. Thoroughly mix and syringe this forcibly into the crevices, and it will, in a great measure, destroy any insects harboured therein. Clean all the old wood thoroughly with the same kind of mixture, using a scrubbing brush for the work, but the young fruitful wood, full of buds, should be more carefully dealt with, sponging these with a weaker solution.

TRAINING.—First regulate the old branches, securing them to the walls at equal distances, and then fill in the bare spaces with the young wood, but not too thickly; when tying allow plenty of room for the swelling of the wood during the coming seasons. Young wood should be carefully preserved all over the trees, and especially at the bottom of the trees, as these can be trained over the old bare branches, and in due time replace them entirely, so that instead of a lot of long, bare, useless wood, good fruitful shoots will cover the walls. Trees which may have been more carefully attended to annually will require much less attention. Remove all ties and shreds likely to pinch the wood, lightly prune, and replace any of the branches to keep the trees in good shape; follow with a good syringing, then remove a little of the surface soil, and finally top-dress with good loam, crushed lime, and manure. Recently planted trees need not be touched for some time; they must be allowed to settle before securing the branches to the walls.

GENERAL WORK.—Although the best time to plant fruit trees is early in the autumn, they may be planted at any time from November to March with good results as long as the weather keeps open and the soil is not too wet and sticky. When planting trees at this season of the year prepare the stations for the reception of the trees, and plant them immediately in case the new soil should become soaked with rain. Trees should never be planted too deeply, especially on heavy land, but the roots should be carefully trimmed and spread out flatly and as evenly as possible. If the soil is too wet a few shovelsful of fine soil from the potting bench spread over and about the roots before filling in with the staple will encourage new roots.

WET WEATHER.—Should the weather be unfit for planting where fruit is grown extensively, there will always be jobs to be done under cover that will be useful at a later date. There are labels to see to, and nets, stakes, and shreds to be made ready, and protecting materials to arrange for. Cuttings of gooseberries and other bush fruit may still be made, labelling these correctly as the work proceeds.—H. Markham, Wrotham Park Gardens.

Selaginellas for Table Plants.—Anyone who has many table and room plants to provide cannot well have too great a stock of those useful selaginellas S. Kraussiana and S. K. aurea. Many gardeners dibble pieces of these in over the surface soil of all plants likely to be called upon for the table, and the practice is an excellent one where strong liquid manure is not used; this latter often kills or browns the selaginella. A first-rate plan is to fill a few shallow pans or saucers with a mixture of equal parts of loam, leaf-mould, and silver sand, and dibble selaginella cuttings in thickly over the surface. In the stove this soon forms a mat of greenery, and it can be drawn upon at will for hiding the bare soil of room or table plants.—E. J. K.

ALLIUMS.

Among the many bulbous plants which are held in comparative neglect by the great mass of gardeners and flower-lovers of all classes are the alliums, or garlics, which, despite the odour so many possess in a more or less marked degree, are much more worthy of cultivation than many would suppose. Not the least of their recommendations is that they generally bloom at a time when bulbous plants are not too plentiful; while the singularity of some of the species compensates largely for the want of the brilliant colouring which only a few of them possess, although the purity of the white of many gives to these a high value in our eyes. One cannot but agree, in looking at some of these, with the words of Ruskin, who said: "The star-group, of the squills, garlics, and onions, has always caused me great wonder. I cannot understand why its beauty and serviceableness should have been associated with the rank scent which has been really among the most powerful means of degrading peasant life, and separating it from that of the higher classes."

Fortunately, however, all the garlics have not this scent in such a pronounced form as others, and there are many which, in our gardens, would be unrecognised as allies of our wild ramsons or garlics because of their beauty, and the onion-like odour being only perceptible when the plant was cut or bruised. Few are really so strong in their odour that it is perceptible without direct contact, and this renders them suitable for many purposes in these modern gardens of ours, which ought to contain at least some representatives of such summer-flowering bulbs as the alliums. They flower over a considerable period, and one may have them from May to August, especially in a year such as the last, when the later species bloomed longer than usual, and one had really good flowers from the genus until long after the middle of August.

It would take up too much space to deal fully with the genus, and even the plants in cultivation and procurable by those intent on securing them, would require more than can be afforded for a class of plants not in high popular favour, so that one must confine oneself to a few of the most useful or those most distinguished for some peculiarity or uniqueness of appearance. Among the species but little known, but yet deserving of more regard, is A. acuminatum, a really pretty species, with good-sized, flattish heads, about three or four inches across, formed of delicate rose-coloured flowers, each about half-an-inch in diameter, and on stoutish stems about a foot high. It is not by any means a scarce bulb, yet it is but little known in gardens, although apparently quite hardy. There is a purple form, of rather less beauty.

Another ornamental allium, but one which seems to dislike a wet winter, as it sometimes goes off in such, is A. azureum, a pretty allium, growing, as a rule, about a foot or a little more high, and giving round heads of deep sky-blue. This is a pretty and useful allium, especially if carpeted with such a subject as the annual limnanthes.

Seldom met with, although cheap, is A. ciliatum, about ten inches high, and giving umbels of an almost flat form of fair-sized white flowers. It is one of the latest to bloom with me. It is said to be synonymous with A. sub-hirsutum, but the plants I have cultivated as such are quite distinct, both in character and in time of bloom.

A little-grown, but worthy species, is A. flavum, which grows about a foot high, and gives umbels of pretty little drooping pale-yellow flowers. It is of slender habit, and would hardly be recognised by the casual observer as a near ally of A. Moly. There is a rose-coloured variety, called pumilum roseum, of some beauty.

I must confess to caring but little for A. giganteum, introduced from Merv more than twenty years ago, which some of us recollect being greatly praised on its introduction. Its stature, three to four feet, seems to the writer its great feature, as its large, globular heads of flower, which are described as lilac, are of the lurid hue which is against so many of the coloured alliums, and the plant is, as a whole, coarse.

One of the quaintest of all my garden plants last year was A. Karataviense, a low-growing species, some nine inches or so in height, but with a large globular head of flowers of an extraordinary character. When in bloom, and seen a little off, it resembles a gigantic head of dandelion in seed, the manner in which the flowers are arranged on the globe, and their greyish colouring lending colour to the general resemblance. It is very distinct from the majority also on account of its broad and glaucous leaves.

A. kansuense, which I used to grow in my last garden, but which I have not at present, is a pretty little species with deep blue, small flowers, and is only a few inches high. It is one which I shall be glad to have again when an opportunity offers.

A. Moly, the old Moly, whose golden flowers look so well in the garden in late May or June, is a much finer plant than many are aware of, its yellow flowers and glaucous leaves looking bright and effective when rising from some dwarf carpeter in the bright days of the season at which it blooms. It is about a foot high. It may be mentioned that practically all the alliums should be carpeted with other plants, as the majority lose their leaves before the flowers are in perfection.

A. neapolitanum, so much used for forcing, is so well known that one need say nothing about its pure white flowers or its value, depreciated, however, by its strong odour after standing in water for a little time. It is fairly hardy, but I have lost it in severe winters, which had wet intervals between the frosts.

A handsome species which few appear to be acquainted with, is A. orientale, which has broad and ornamental glaucous leaves and long stems some two feet high, surmounted by a good, flattish head of creamy-white flowers. This is a good garlic of considerable beauty.

A. Ostrowskianum is now fairly well known, and gives us good, deep rose, or pale purple flowers in drooping umbels. It grows some eight or nine inches high, and is generally confounded with A. oreophilum, a dwarfer plant. A. pedemontanum, of somewhat similar character, is one of the prettiest of the genus, and an excellent plant for the front of the border or the rockery.

The old A. roseum, with nice umbels of rose-coloured flowers on stems a foot or more in height, is hardly ever met with now, save in a botanic garden. It remains one of the most useful of the genus.

A. Schuberti, an extraordinary-looking plant, especially when in seed, was introduced about nine years ago, but has not yet become well known. It has what is termed a sub-globose head of flowers on long stalks, and is quite ray-like in appearance. The flowers are purple. I have not found this very hardy, over a period of years, but it is such an extraordinary plant that it is well worth growing.

A. sphærocephalum is a late bloomer, coming in for August, and even for September bloom. It has long stems about two feet high, each with a globe of little flowers at the summit. These open from the top and are purple. It is too long in the stem for the size of the heads, and should be grown with a tall carpeter.

A. stipitatum, whose acquaintance I made last year only, is a good and distinct allium, with stems about two feet high, and having a globular umbel of violet purple flowers on longish stalks. It has handsome leaves, but these are past ere the flowers open. This is a species well worthy of notice. A. sub-hirsutum, already referred to in connection with A. cernuum, is one of the most beautiful of the white-flowered varieties, with rigid stems, and when seen in a good group, very pleasing.

Few among the species are more beautiful than A. triquetrum, which has triangular stems about a foot high, carrying umbels of pure white-drooping flowers. This is a very hardy and ornamental garlic, a little strong in odour when bruised, perhaps, but not obtrusive in itself.

One might have discussed other species, of which there are many, but these are some of the most easily procured, and a selection from them will give a pleasing variety in the garden. Their culture is easy, as the greater number will thrive in any good garden soil, preferably of a rather light nature. They should be planted from two to three inches deep, according to the size of the bulb, as early as they can be procured in autumn.

S. Arnott.

ALTHÆA PONTICA.

In common with many gardeners who take active interest in the planning of gardens, I have often had occasion to use quick-growing plants of giant stature as a temporary screen (in the case of new gardens), or as a means of filling the troublesome gaps that occur in old shrubberies. For many years I used bocconia and kindred plumy plants, and right well they filled their office, but when colour was wanted in connection with stature, selection was limited. A giant species of hollyhock (Althæa pontica) is one of the few plants I can recommend for this purpose. It must have plenty of room, full light everywhere, and a tolerably rich soil; with these requirements fully met, it will reach sixteen to twenty feet in height, every few inches of the many stems will bear a large, refined rose-pink flower typical of hollyhock in shape, but seemingly of a more attractive colouring than many hybrid varieties, and they give the impression of being stouter in substance than really is the case.

This althæa has one good feature that will appeal to many who fail to grow hollyhocks; it is not debilitated by disease. It is not immune, however, far from it, but a few spots here and there are nothing when the exceptional vigour of this species is taken into account. It is a good perennial, but does not reach full stature till the second year, hence those who may have occasion to plant it must keep a few seedlings in the reserve garden to draw upon as they may be wanted. Its greatest use in the garden is in the furnishing of shrubbery gaps. A cluster of leafy spikes thickly studded with flowers, towering through an ugly gap, impresses one with its value.

G. B. Mallett.

A TALK TO GARDENERS.

In commencing my talk to gardeners, let me first say that I am a gardener of the single-handed class, which is by far the most numerous in the country. I have a garden two acres in extent to look after, and this is so arranged that there is a fruit and vegetable garden of one acre, and a similar area devoted to lawns, shrubbery, rosery, flower beds, and herbaceous borders. I think this fairly represents the average gardener's place throughout England. Anyway I feel assured that everyone will agree it is quite enough for one man to manage, even with occasional help in the summer. I have been here six years, so I presume I "give satisfaction."

It will be generally agreed that nothing disheartens a gardener so much as to find his work not appreciated, and especially if he is conscientiously doing his best. But in my opinion it is very often the gardener's own fault when this is so. He may have learnt his business in every detail as an under-gardener, or he may have been in one place a considerable number of years, and when entering on a new charge he finds himself called upon to carry out a quite different style of gardening. If he persists in working on the same lines as those followed in his previous place he will very likely have to bear with some amount of unpleasantness. Different persons have different tastes, in gardening as well as other things. Let the gardener in entering on a fresh charge find out what his employer's wishes are with regard to his garden, and then devote himself to carrying them out. Employers are generally willing to tolerate any shortcomings on the part of the gardener if they can see him trying to do things in accordance with their wishes. He should put his own views entirely on one side, and endeavour to look at the garden from his employer's standpoint.

A gardener, it should be remembered, requires great patience and tact in dealing with the different members of the household. Take first the master, who is often away at business all day. He may be an enthusiastic gardener himself, or he may not, but in any case, he will like to see the garden neat and tidy when he is at home on Saturday afternoons and Sundays. He can then find pleasure in taking his friends round, as he will not find anything to give him annoyance. An employer does not like to hear grumbling from the gardener as to how hard he has to work, and so on. If he brings home a tree of any kind or a flower root, he has much interest in seeing it grow, and though the gardener may look upon it as of no account, he will do well to give it every attention, and make the best he can of it.

There is also the lady of the house to be considered, and, as a rule, whether she understands gardening or not, she will require plenty of flowers for house decoration, and the gardener will be wise if he devotes special attention to the work of supplying them, and makes careful note of what flowers are preferred. Although the gardener may not like to see the garden partly denuded of flowers for the time being, he should remember that they look well in the house, and meet with more attention and receive greater admiration than they would have done had they been left on the plants. If there are any grown-up sons they will not, generally speaking, overlook the possibility of the place providing them with games of some kind, and this should be kept in mind.

Again, the daughters must have due consideration. They will probably want to play tennis or croquet, and may be they will bring seeds that they have had given them, and want the gardener to see what he can do with them. If there are young children they may want to do a little gardening, and if this is the case they should not be frightened off, as so often is done. To see a bulb or a tree grow which they have planted themselves gives them the greatest enjoyment. Too often the gardener throws cold water on their little efforts. They always remember the manner in which the gardener treats them, and when they have the chance they treat him accordingly.

In conclusion, let me say that when gathering vegetables they should always be so prepared as to reach the kitchen in a clean state, without waste. If this is not done there will surely be complaints about them. This all helps to show what a self-sacrificing occupation that of the gardener's is, but if he has to sink his own personal feelings in gardening he will have his reward in seeing those by whom he is employed happy in the enjoyment of their garden.

H. Roberts.

Bentley Heath,, near Knowle, Birmingham.

BACTERIOSIS IN WINTER-FLOWERING CARNATIONS.

A correspondent of the "Weekly Florists' Review" writes concerning Stigmonose or Bacteriosis, as follows:—

This disease seems to be the final undoing of more varieties than any other disease or cause, and that in spite of the fact that we know to a certainty how it is introduced into the plants' system and that it could be prevented. It must be admitted that it is directly caused through carelessness on the part of the grower in keeping down insects. While it is almost impossible to keep the plants absolutely free from thrips, red spider, and aphis, yet the careful grower will allow so few of these pests to live that there will not be enough punctures to injure the plants perceptibly. A plant will bear a moderate amount of these punctures without showing any deterioration, but if they are too numerous the drain on its vitality is too severe, and a breakdown of the cell structures is sure to follow. This is especially true of new varieties.

A plant which is started from seed is entirely free from this disease until it is inoculated through insect punctures. This may happen any time after germination. A plant which is raised from a cutting may have been infected when the cutting was taken from the old plant. In fact it is almost sure to have some of the poison in it, if the old plant showed any signs of it. The more of these light spots that show, the more is the disease getting the upper hand. So, after a plant is once infected, it is entirely a question of cutting selection, attention to insects, and careful growing being only natural, whether there is disease or not. Spraying with fungicides or germicides, or fumigating, will do no good. If the cuttings are taken indiscriminately, regardless of the amount of disease they contain, it will become worse each season until it destroys the whole stock; whereas if the cuttings are selected carefully, and only such taken as show no spots whatever, and this is followed up each season, the disease can be worked out of the stock entirely. As I have said before, the value of a variety must determine whether it is worth the trouble. New and improved varieties come along so rapidly that unless a variety is unusually good it would pay better to discard it entirely if badly infected.

It is sometimes stated that the presence of this disease signifies that a variety is getting old and less vigorous. I do not agree with this theory. The only thing it proves is that there has been carelessness on the part of the grower in keeping down insects and in the selection of cuttings. There is, however, considerable difference in varieties. Those which have a hard surface and firm growth in general will not succumb so easily as those of a softer nature. That is why some varieties never show this disease at all, while others will show it when you get them from the originator.

One thing which the presence of these spots does prove, however, most conclusively is, that unless great care is exercised the variety will not last long.

HARDY FLOWERS are always popular, as they make the garden bright and attractive, and require but little attention. All the information required for their successful culture is given in EASILY GROWN HARDY PERENNIALS. The Publisher of THE GARDENERS' MAGAZINE will send you a copy from 148-149, Aldersgate Street, London, E.C., by post, for 5s. 6d.

ERADICATION OF FAIRY RINGS.

With reference to the injurious effects of fairy rings on turf, which were the subject of an interesting note in the "Journal" of the Board of Agriculture for August last, Mr. G. H. Robinson, assistant vegetable pathologist, Victoria, states that of all the causes which operate against the formation and maintenance of a good, even turf in bowling greens, golf links, and lawns in general, none is more potent, in Melbourne and its suburbs, than the fairy ring puff-ball (Lycoperdon polymorphum, Vitt.). For ten years or more the fungus has been defying the efforts of the caretakers of the Melbourne bowling greens to eradicate it, and until recently nothing short of digging out the affected areas was regarded as satisfactory. Such a method, though practicable where the rings are few and small, is out of the question when large and numerous, owing to the difficulty of securing a level surface after the work, and in a green so treated the remedy would probably be worse than the disease. Within the last two years, however, a cheap and effective method of eradication has been found, so that the fairy ring ceases to occupy the position of a dangerous enemy, and may be regarded as a parasite easily destroyed.

It may be mentioned that the name of "fairy ring" has been given on account of the curious effect of the fungus upon the grass where it is found. The spawn of the fungus draws its nourishment from the roots of the grass, and spreads always in an outward direction to all points of the compass, so that shortly after a green has been infected, and during the latter part of summer, a number of darker-coloured, narrow circular bands or rings may be seen, less than a foot wide, but with a diameter of a few or several feet. In these rings the grass is at first so much deeper in colour than the rest that they are easily seen from a considerable distance. It used to be said that this richer green was due to the dancing of fairies; hence the name fairy rings. Soon, however, a change for the worse is observed; the grass in the ring becomes thin, though still retaining its deeper hue; much of it dies away, resulting in an uneven surface, and a great number of small puff-balls are formed. If the grass is swept and rolled every day these puff-balls often escape notice, since in such cases they scarcely exceed the size of a pea; but, growing unchecked, they may reach a diameter of an inch or more, and may be nearly two inches high.

About ten years ago Mr. McAlpine, vegetable pathologist of Victoria, made some experiments with various fungicides, and it appeared that a solution of sulphate of iron might overcome the disease, but the experiments were not conducted long enough to be conclusive. In April, 1905, Mr. G. H. Robinson was requested to make an effort to eradicate the pest on a bowling green in Victoria. Some preliminary trials were then made on a small scale, plots being treated with a solution of iron sulphate, Bordeaux mixture, copper-soda, and copper sulphate solution. It was soon found that mixtures like Bordeaux and copper-soda with their bulky gelatinous precipitates, were useless for the work, for the material could not be made to permeate the soil so as to reach the spawn of the fungus. Of the others, a copper sulphate solution of one ounce per gallon, using half a gallon per square yard on three occasions a week apart, was found to injure the grass before eradication was complete. Fortunately, the plot treated with sulphate of iron was doing well, no puff-balls appearing after three applications of a solution of rather less than one pound in five gallons of water at intervals of a week, though, of course, it was then impossible to say whether the fungus had been entirely destroyed. The only sure sign of eradication is the absence of fairy rings and puff-balls in the next season.

The measure of success achieved with sulphate of iron appeared sufficient to justify its use over the whole green, the rings being then so numerous that it is doubtful if an area of thirty square yards was free of them. The green was therefore divided into plots of sixty square yards, putting on that area eight pounds of sulphate of iron dissolved in thirty gallons of water. The solution was made in barrels and applied with ordinary zinc watering cans, one man using two at a time, one in each hand. The evening previous to the application the green was well watered, and after the solution was applied a further light watering was given to assist to convey the solution down to the roots. The green was closed two days prior to the first application, and it was found that where much trampling had occurred when play took place the iron sulphate blackened the grass to some extent, but no lasting injury resulted. Little effect was observed from one application beyond a deepening of the colour of the grass and a marked reduction in the number of puff-balls.

Three additional treatments were given, four in all, at intervals of a week, and only two puff-balls were gathered on the whole green after the second dose, though before the first it would have been no hard task to collect a barrowful. Since the third treatment no puff-balls have been seen on the green, and two whole seasons have passed with no trace whatever of anything in the shape of a fairy ring. Owing to the large amount of sulphate of iron used, over a ton to the acre, it was deemed advisable to give a heavy dressing of lime to reduce any remaining in the ground to a harmless state. A week after the last application, quicklime, freshly slaked to a fine powder, was evenly spread over the surface at the rate of one ton per acre.

The success of these operations was so pronounced that other greens similarly affected were treated last autumn. A few precautions should be taken by those who try this method. Chief amongst them is the necessity for keeping the ground moist, while on no account must the dressing of lime a week after the last treatment be omitted. The area to be treated is better left without rolling, and it is well to cut the grass only once a week during the work, say two days before each application. Though four doses were given, it is possible that three would prove sufficient, but less than that might leave some spawn uninjured in the soil to form the centre of another outbreak. The autumn—when the fungus is actively growing—is the proper time for the work; in the height of summer, or in the depth of winter, the prospects of success are not so good, while the risk of injury to the grass is greater.

Chrysanthemum inodorum Bridal Robe.—Annual flowers hardly ever come amiss in the garden, whether employed as bedders or grown among perennial flowers, either as a supplement to their beauty or for securing plenty of bloom at seasons when the perennials may give some gaps in their succession. Useful as it is valuable, Chrysanthemum inodorum plenissimum, the new variety, called Bridal Robe, which I had the pleasure of making the acquaintance of last year, is very beautiful indeed. As a bedder it will prove almost unsurpassed where a close array of pure white is required. The flowers, like large double daisies, are produced in enormous numbers, and are of the very purest white, the whole, when massed together, giving a snow-like effect to the bed. The great doubleness of the blooms has the effect of prolonging the time of flowering, and one can hardly conceive any of the annuals of recent introduction as being likely to achieve a higher place in the estimation of those who desire a good bedder of this character and growing from nine to twelve inches high. It comes true from seed, and may be raised in the ordinary way of other hardy annuals.—S. A.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Ninepence per line, the minimum charge being Five Shillings. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

British Gardeners' Association.

At the last meeting, held on December 31, nine new members were elected, making 1,128 since the establishment of the association. The secretary reported that the last issue of the "B.G.A. Journal" had been posted to every member, both at home and abroad. The design for the members' certificate was adopted, and, it is hoped, this will be ready for issue in a few weeks. The report of the Richmond and District branch for the past year was received and discussed, and will be printed in next issue of the association's "Journal." Gardeners are reminded that the B.G.A. is confined to qualified gardeners only, and that new members may join at any time, provided their credentials are up to the required standard. Forms can be obtained from the Secretary, B.G.A., Talbot Villa, Isleworth, W.

Bristol Gardeners' Mutual Improvement Association.

The usual fortnightly meeting was held on Thursday, January 2, at St. John's Parish Room, and was presided over by Mr. A. O. Shelton. The lecture was upon "Butterflies and Moths," and was given by Mr. L. Stafford, Caerleon, Mon., representative of the Newport Gardeners' Association. Mr. Stafford is an enthusiastic entomologist, his collection comprises practically all the British species and varieties of butterflies and most of the moths, the result of nearly twenty years' work. The lecturer had fourteen cases of insects on view, which added interest to the lecture, and for these he was awarded a special certificate. Mr. Stafford said there are from sixty to seventy kinds of British butterflies, and hundreds of moths; they belong to the order of Lepidoptera, and are true insects, because they pass through four stages—egg, caterpillar, pupa, and imago, the latter of which have three divisions—head, thorax, and abdomen. The female insect will fly for miles to find a suitable tree or plant on which to deposit its eggs, and thus ensure food for the caterpillars when hatched. These will devour two or three times their own weight in a few hours, and whose aim is to prepare for the next stage—the pupa—from which the perfect insect emerges. The lecturer was accorded a very hearty vote of thanks. For two primulas Messrs. Shelton and Curtis were placed respectively first and second.

Tonbridge Gardeners' Society.

At the annual meeting of this society, which was held at the Bull Hotel, with Councillor T. Ives in the chair, and Mr. C. Milner in the vice-chair, a satisfactory report was presented to the members. The receipts for the year, with the balance of £1 10s. 5d. from the previous year, amounted to £110 11s. 11d. Of this sum £43 14s. 6d. were subscriptions, and £28 6s. gate money. The expenses were £106 8s. 9d., including £3 10s. sent to the Royal Gardeners' Orphan Fund, and £45 12s. paid in prizes, leaving a balance in hand of £4 3s. 2d. Both report and balance-sheet were adopted. The chairman, vice-chairman, treasurer, auditors, and secretary were re-elected, and Messrs. Dann, Lawrence, Ireland, Humphrey, Webler, Russell, Remnant, Keale, and Orrom elected as members of the committee. The chrysanthemum show was fixed for November 11 and 12, when about £50 will be offered in prizes.

NOVELTY IN ROSES.

In addressing the Chicago Florists' Club on the occasion of its December meeting, Mr. E. G. Hill, the well-known rosarian, of Richmond, Indiana, U.S.A., said: "Anything new in roses?" is a question propounded much more frequently now than a few years ago, especially by the rose growers of America, and the same question is asked with even more interest in Europe.

The rose growers, he said, charge the retail store men with being more largely responsible than themselves for the seeming indifference toward new varieties, and in this there is undoubtedly a considerable degree of truth, but it must be confessed that a large number of florists, including the growers, have shared in this indifference. In the light shed on the matter of novelty by the milliner, the silk manufacturer, the dry goods man, and, in fact, by all the vendors of apparel, ornament, and furniture, it is surprising that the florists should have been the reactionaries in the matter of novelty in roses, but we have to admit that such has been our past record.

Novelty in Roses is Being Sought.

It was a leading society lady who gave utterance to the protest against being compelled to use Bride, Maid, or Beauty for her frequent functions. Her criticism was only too well justified, and she simply voiced the general complaint concerning the world's pre-eminent flower, the rose. But a change has recently taken place and new varieties are given a very different reception from that accorded a few years ago. It is well for the rose that such is the case, else the carnation would have continued its triumphant march to the point of disputing leadership with the rose.

Believing that a radical change has taken place, and that novelty in roses is being sought, the question arises: Shall we be able to meet reasonable expectations, and can we provide new varieties so as to satisfy this greater interest? The answer is in the affirmative, and it is a pleasure to record that a considerable number of workers are endeavouring by hybridisation and cross fertilisation to give to the rose-loving public new forms and types.

So many qualities have to be present in a rose that lays claim to favour as a forcing variety that the progress made will seem slow, but, nevertheless, it is within the range of possibility to gain entirely new and unique colours and forms.

Future Efforts.

I believe, said Mr. Hill, with Mr. Robert Simpson, the present president of the American Rose Society, that the forcing roses of the future will come largely from an admixture of Rosa indica with the present hybrid perpetuals. In fact, do not the hybrid teas bear witness to this prophecy? Still, the strong old Bourbon varieties, like Gloire des Rosomanes, should be made to furnish their rich scarlet tones to the newer sorts. Our task is to breed into the tea varieties the strength, vigour, length of stem, and the finer dark shades found among the hybrid perpetuals, using the tea section in order to secure freedom in flowering. The varieties of the future will not be the result of a single cross between the two sections named, but will be the result of patient interbreeding, extending through a series of years. Here and there a desirable new variety may make its appearance as a result of a haphazard cross, but to get at definite results we must make careful note of the qualities present in the progeny and then seek to breed those missing qualities into future seedlings.

We must not forget that Rosa indica is the one class that is to furnish the foundation for all our forcing varieties, and this is on account of its continuity of bloom. No matter how fine a rose, or what the tint or length of petal, unless it has the inherent power to produce buds and flowers freely it will prove practically valueless. We have every reason to hope that we may yet possess the ideal from the careful crossing of the hybrid perpetuals and the teas. We have Richmond, Mme. A. Chatenay, Liberty, Killarney, all undoubtedly from this source; hence it is within reason to hope for others in this particular line.

Peculiarities of New Varieties.

The new varieties appearing will perhaps require more careful treatment, or at least different cultural treatment from that given our present forcing varieties. The new varieties will require study; perhaps some will thrive best grafted on certain stocks, or will do best in certain soils. A case in point is the variety Killarney. It was Mr. B. Dorrance who discovered the peculiarities of this variety and who brought it into its present prominence. It would be well, therefore, to give new varieties a careful trial before casting them aside. My conviction is that we have much to learn in regard to right cultural conditions. I am inclined to think that perhaps other valuable varieties have been lost sight of by their not having had proper cultural treatment. We know that to grow American Beauty successfully requires the application of good cultural skill, and very often this variety fails to give best results in the hands of the most skilful growers. Great progress has been made in methods of culture, and you have some notable examples in this line in your own vicinity. I mention the cultural side of the question in order to show how important it is that new introductions shall not be condemned too hastily.

Some fairly successful rose men still inveigh against Killarney and Richmond, because they cannot do them successfully, and it is only the fine showing made by a majority of our best growers that has given these roses the position they deserve. Each new rose must be studied and results carefully noted, before its cultural requirements can be known. It is infinitely easier to master the peculiarities of two or three sorts, drop down into a rut with them, and run along comfortably, than to experiment, and fail, and try again. Experimental work is seldom comfortable work, but buyers demand novelty and variety, and there is nothing for it but for us to take off our coats and do our best to provide what is demanded of us.

Golden Wedding Celebration at Edinburgh.—Messrs. Dicksons and Co., 1, Waterloo Place, Edinburgh, entertained their employees at the Craigmillar Nurseries, on the occasion of the golden wedding of Mr. William McAra, one of their nursery overseers. Mr. Welsh, one of the partners, presided over a company of sixty, and in a few words of congratulation to Mr. and Mrs. McAra presented them with a purse of sovereigns, which had been subscribed by Mr. McAra's fellow workers. A dance followed, and altogether a very enjoyable evening was spent.

A New Work on Sweet Peas.—During 1907 there was a marvellous development of sweet pea culture, and a wonderful advance in the form and colour of the new varieties of our most popular hardy annual. At this moment there comes most opportunely an attractive, useful, and entertaining little book on "Sweet Peas and Their Cultivation for Home and Exhibition," by Mr. Charles H. Curtis, F.R.H.S., hon. secretary of the National Sweet Pea Society. The history and evolution of the sweet pea make up an interesting story, and these are followed by chapters dealing concisely and clearly with seed sowing, ground preparation, methods of staking, manuring, how to raise new varieties, how to cut and pack the flowers, and how to win prizes. There are lists of the best varieties, and of too-much-alike varieties, consequently one discovers what to grow and what to avoid. The book is freely illustrated, and it is published this week by Messrs. W. H. and L. Collingridge, 148, 149, Aldersgate Street, London, price one shilling (by post 1s. 2d.), or bound in cloth 1s. 6d., by post, 1s. 8d.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

PENTSTEMONS.—H. C. N., Cheshire: We do not know whether the strain you mention is in commerce; but if you write to Mr. E. Beckett, Aldenham House Gardens, Elstree, we have no doubt that he will give you the required information.

BEGONIA GLOIRE DE LORRAINE.—R. M., Sussex: You have not been correctly informed with regard to the origin of this begonia. It was raised by M. V. Lemoine from a cross effected between Begonia socotrana, which, as stated in our issue of the 4th inst., was discovered by Professor I. Bayley Balfour, when exploring Socotra, and B. Dregi a species that had long been in cultivation. It was distributed in 1892.

GARDENERS AND THEIR WORK.—H. R., Birmingham.—We are much obliged by your communication and appreciate the spirit in which it is written. A frank discussion among gardeners regarding their position, duties, and so forth can hardly fail to prove useful to all concerned, and help to maintain the good feeling which happily so generally exists between employers and their gardeners. This good feeling is largely due to the strenuous efforts that are made by gardeners as a body to proceed on lines that are in full accordance with the requirements and wishes of their employers.

PRUNING GRAPE VINES.—G. S., Hampshire: It is a good rule to prune grape vines on as early a date as convenient after the leaves have fallen. When pruned thus early there is sufficient time for the cuts to heal before the sap begins to rise. When the pruning is delayed until this stage there is some difficulty in preventing "bleeding," which, if not checked, has a weakening effect upon the vines. The few bunches of grapes remaining upon the vines should be cut with some seven or eight inches of the lateral below the bunch. For keeping them in good condition until required for use, suspend bottles in the fruit-room, place two or three small pieces of charcoal in each, and fill to the neck with clean water. Then place the lateral of each bunch in a bottle and just deep enough for the bunch to be quite free from the neck of the bottle.

FUCHSIAS FOR BEDDING. — W. B., Yorks: As you require plants between two and three feet high when you bed out at the end of May, it will be necessary to commence the propagation of a stock early in the year. We suggest that within the next fortnight you prune the old plants of the varieties you require, and place them where they will have the assistance of a temperature ranging between 50 and 60 degrees. With moderate waterings at the roots, overhead syringings, and the temperature suggested they will soon commence to make stout growths, which in due course may be taken off and rooted in accordance with the usual practice. It is essential to success in the production of strong bush or pyramidal plants for bedding to have stout growths for cuttings and to maintain a steady growth throughout by means of a temperature not greatly exceeding 60 deg.; except during bright, hot weather, when an additional 5 or 10 deg., with free ventilation, may be allowed. A rather rich compost should be used, and after the plants have filled with roots the pots into which they are put when they receive their final shift, weak liquid manure may be occasionally used. Free ventilation and but little, if any, shade are important points in the production of fuchsias with firm short-jointed growths.

PLANT RUSTS.—Warrington, Subscriber: The fungi causing the diseases known as carnation rust and chrysanthemum rust are quite distinct from each other, and according to the present stage of knowledge of them, there is no danger of the carnation rust attacking the chrysanthemum, and vice versa. The first of the two rusts (Uredo dianthi) is the most destructive to plants when grown in an insufficiently ventilated house, and the chrysanthemum rust (Puccinia hieraci) is usually most prevalent in dry seasons, such as that of 1898, when it spread so rapidly in collections both in England and on the Continent as to cause much anxiety to chrysanthemum growers generally. You do not give either name or initials in your letter. Your name should have been given, not necessarily for publication, and if not that, initials or a nom de plume is essential to enable us to indicate the correspondent for whom the answer is intended.

WINTER-DRESSING OF FRUIT TREES.—R. A., Winchester: There can be no question that the present season of the year is by far the best in which to make an effort to eradicate the pests of fruit trees. The trees are now dormant, and insecticides can be used that in the spring, summer, and autumn months would be most destructive to the trees. Your apple trees are infested with that troublesome pest, the woolly aphis or American blight, and your pear trees are not less seriously infested with the oyster scale, which is so objectionable because of it spreading to the fruit during the summer months. We therefore strongly advise you to commence operations at once with a view to the eradication of the pests. You may not be able to effect a complete eradication, but you will be able to so reduce them as to prevent their doing any considerable amount of injury, and thus prepare the way for their extermination next year. A solution of caustic soda and caustic potash has been used with good effect in winter for many years past. This is prepared by dissolving half a pound of caustic soda (Greenbank's 98 per cent.) and half a pound of crude commercial potash in five gallons of water, and is applied during the winter in the form of a fine spray. You must use a pair of thick gloves when you are spraying the trees to prevent injury to your hands. As the result of the experiments carried out at the Woburn Experimental Fruit Farm, a mixture prepared with copper sulphate, caustic soda, quicklime and paraffin is recommended, and if you would like to give it a trial we will give you the necessary particulars. In your case it will probably be well to confine your attention to the older remedy. An excellent dressing for use at this season on both apple and pear trees is prepared as follows. Put 4oz. of hard soap into one quart of water, and heat the latter until the soap is dissolved. Then add one pint of paraffin oil and agitate the whole until an emulsion is formed. To the emulsion add water in sufficient quantity for the paraffin to be in the proportion of one to fifteen. Apply with a brush, and well work it into the crevices of the bark and wood, that none of the pests may escape.

PEAR CULTURE UNDER GLASS.—Amateur, Lincoln: The cultivation of dessert pears under glass is not so simple a matter as the glass culture of peaches and nectarines. Unlike the two last-named kinds, which ripen their fruits in the most perfect manner when grown throughout under glass, the pear requires during the ripening process full exposure to outside atmospheric conditions to ensure the fruits attaining their full flavour. The cultivation of pears under glass has much to recommend it, especially where, as in your garden, the wall area available for these fruits is extremely limited. With good management excellent crops can be depended

The Four Best Books
ON VEGETABLES FOR PROFIT.

Edited by T. W. SANDERS, F.L.S., F.R.H.S., Editor of "Farm and Garden."

ONE SHILLING EACH NET, BY POST 1/2.

Bound in Cloth, **1/6** net, by Post **1/9.**

No. 1.

GREEN CROPS:
Broccoli, Cabbage, Cauliflower, Brussels Sprouts, &c.

A Practical Treatise on the Cultivation of Green Crop and Herbs for Market, and Best Methods of Packing and Marketing the Crops; Pests and Diseases attacking Green Crops, and How to Eradicate Them, &c.

CONTENTS OF No. 1.

Green Crops: Borecole or Kale—Broccoli—Brussels Sprouts—Cabbage—Cauliflower—Colewort—Savoy—Spinach.

Herbs: Angelica—Anise or Aniseed—Balm—Basil—Borage—Chives—Chervil—Chamomile—Caraway—Dill—Fennel—Horehound—Hyssop—Lavender—Marjoram—Mint—Parsley—Rosemary—Rue—Sage—Savory—Tarragon—Thyme.

Pests and Diseases, AND HOW TO ERADICATE THEM: Cabbage Aphis—Butterflies, Moth, Yellow Underwing Moth—Fly—Gall Weevil—Snowy Fly—Club Root—Seedling Cabbage Disease—Black Rot in Cabbage—Mint Rust—Spinach Mould.

Miscellaneous: Manures (Animal and Artificial)—Number of Plants per Acre—Approximate Yield per Acre—Piecework Prices—Market Measures—Average Prices of Green Crops—Pickling Green Crops—Rating Market Gardens—Legal Definition of Market Gardener—Compensation for Crops, &c.—Drying Herbs—Yield and Prices of Herbs—Prices of Chemical Manures, &c., &c.

No. 2.

ROOT CROPS:
Potatoes, Carrots, Turnips, Onions, Beet, &c.

A Practical Treatise on Planting and the Cultivation of Roots, Bulbs, and Tubers; Lifting, Storing, and Marketing the Crops; a full description of the various Pests that attack such Crops, and Best Remedies for their Eradication, &c.

CONTENTS OF No. 2.

Crops: Beet Root—Carrots—Celeriac—Garlic—Horse Radish—Jerusalem Artichokes—Kohl Rabi—Leeks—Onions—Parsnips—Potatoes—Salsify and Scorzonera—Shallots—Turnips.

Pests: Beet Carrion Beetle—Mangold or Beet Fly—Onion Fly—Parsnip and Celery Fly—Wireworm—Carrot Fly—Red Spider—Wasps—Turnip Leaf Miners—Heart and Dart Moth—Common Dart Moth—Turnip Gall Weevil—Turnip Sawfly—Turnip Fly—Turnip Aphis—Diamond Black Moth.

Diseases: Beet Rust—Carrot Disease—Finger and Toe Disease—Onion Scab—Onion Sclerotina—Onion Smut—Turnip Bacterial Disease—Onion Mildew—Parsnip Disease—Potato Disease—Potato Rot—Potato Scab.

Miscellaneous: Quantities of Seeds per Acre—Yield of Produce Per Acre—Longevity of Seeds—Cost of Cultivating Crops—Time Required for Germination of Seeds—Average Market Prices of Vegetables—Market Measures—Manures—Analyses of Vegetable Ash, &c., &c.

No. 3.

ASPARAGUS, BEANS, PEAS, MARROWS, CELERY, &c.

A Practical Treatise on the Culture of Peas, Beans, Rhubarb, Celery, Asparagus, Marrows, &c.; Soils and their Treatment; Pickling and Preserving the Crops; Pests, Diseases, &c.

CONTENTS OF No. 3.

Crops: Asparagus—Broad Beans—Cardoons—Celery—Globe Artichoke—Kidney Beans—Peas—Rhubarb—Ridge Cucumbers—Runner Beans—Sea Kale—Vegetable Marrows.

Pests: Aphides—Asparagus Beetle—Bean Aphis or Dolphin Fly—Cockchafer Beetle or May Bug—Celery Fly—Millepedes—Pea and Bean Thrips—Pea Midge—Pea Moth—Pea Seed Weevil—Pea Weevils—Red Spider—Slugs and Snails—Wireworm—Woodlice.

Diseases: Asparagus Rust—Canker and Rot—Celery Leaf Blight—Cucumber Mildew—Mildew—Pea Mildew—Pea Spot—Seedling Pea Blight.

Pickling and Preserving: Green Peas—French Beans—Gherkins—Rhubarb Jam—Vegetable Marrow Jam—Rhubarb Wine.

Soils and Their Treatment.—Clay—Loam—Sandy Soils—Peat Soil—Colour of Soil—Testing Soil for Water—Paring and Burning Soils—Composition of Soils.

Miscellaneous: Quantities of Seeds or Plants per Acre—Average Yield per Acre—Seed Testing—Analyses of Vegetables (Ash)—Average Prices of Produce—Cost of Soil Cultivation—Hedge Planting—&c., &c.

No. 4.

MUSHROOMS, CUCUMBERS, SALADS, TOMATOES, &c.

A Practical Treatise on the Cultivation of Cucumbers, Mushrooms, Tomatoes, Watercress, Salads, &c.; Preparing and Packing for Market; Pests and Diseases, and How to Eradicate Them.

CONTENTS OF No. 4.

Crops: Chicory—Corn Salad or Lamb's Lettuce—Cucumber—Dandelion—Endive—Lettuce—Mustard and Cress—Mushrooms—Radishes—Spring Onions—Tomatoes (Indoor)—Tomatoes (Outdoor)—Watercress.

Pests: Ants—Aphides or Green Fly—Birds—Lettuce Fly—Lettuce Root Aphis—Mushroom Pest—Onion Fly—Radish Fly—Radish and Turnip Flea Beetle—Red Spider—Slugs and Snails—Snowy Fly—Surface Caterpillars and Grubs—Tiger Moth—Thrips—Wireworm—Woodlice.

Diseases: Bacterial Disease of Tomatoes—Black or Brown Stripe Tomato Disease—Cucumber Leaf Blotch Disease—Cucumber and Melon Mildew—Eelworms—Finger and Toe Disease—Lettuce Mildew—Mushroom Disease—Potato Disease in Tomatoes—Radish Mildew—Sleeping Disease in Tomatoes—Tomato Black Spot or Rot—White Rust—Yellow Spot Tomato Disease.

Glass-houses: Market Glass-houses—Tomato House—Cucumber House—Cost of Building Glass-houses—Cubical Contents of a Glass-house.

Miscellaneous: Market Measures—Formulæ for Insecticides and Fungicides—Average Prices of Produce—Analyses of Animal Manures.

upon annually, and a house of moderate or larger size devoted to pears will give an ample return. For the reason already indicated, portability is essential to success, and therefore the trees must be grown in pots. The trees make a satisfactory growth and produce good crops, and ripen their fruit when grown wholly in a glass structure, but the fruits are more or less inferior in quality, as compared with those of trees grown wholly or in part out of doors. With the trees in pots you can keep them out of doors with their pots plunged in a bed of ashes, or partly-decayed leaves, until the flower buds are beginning to swell freely. They can then be taken indoors and the house in which they are placed be freely ventilated at all times, excepting in frosty weather. They ought not to have fire-heat, excepting in frosty and in humid weather, and then only sufficient to keep the embryo fruits safe from frost or maintain a dry, buoyant atmosphere, as the case may be, the latter being essential to the fruit setting freely. You should keep the trees indoors with abundant ventilation until about the middle of June, when they should be placed in the open upon a bed of coal ashes or a hard surface and have coal ashes or partly-decayed leaves placed about the pots, to prevent the soil drying too quickly. When they are in the open you must protect the fruits from the birds, and efficient protection can be afforded by means of a few light strips of wood and old fish nets, securely fixed at such distance from the branches as will render it impossible for the birds to reach the fruits. The trees will require careful watering, and from the commencement to the completion of the growth, rather liberal supplies will be necessary. The soil must not be allowed to become quite dry, or be kept in a constantly saturated state, for either extreme is injurious. The growths must be thinned, as in the case of trees outside, and be stopped two or three times, the first stopping to be done when the shoots are five or six inches long. The trees, when carrying good crops, will require top-dressing two or three times with some approved artificial fertiliser, or occasional supplies of weak liquid manure.

Chrysanthemum F. S. Vallis.—The popularity of this Japanese chrysanthemum has not been excelled by any other variety, excepting perhaps Madame Carnot, which was also one of Calvat's seedlings, and, the flowers being white, it would naturally be a trifle more sought after than any yellow chrysanthemum. "C. H. P." has undoubtedly seen some monster blooms during his sojourn in Paris. We here are content to obtain blooms twelve inches in diameter, but "C. H. P." records them at four inches more than that! I wonder whether these huge blooms were grown in the Roubaix district?—Sadoc.

Sweet Peas in Cold Frames.—The practice of raising sweet peas in cold frames is now fairly common, so that the note of warning below will appeal to many readers. It is this: Do not be misled by the fact that the sweet pea is hardy to allow frames to go unprotected on frosty nights. When confined in pots the roots are not hardy, the pots attracting frost. Last year a noted grower sent me plants of sweet peas for opinion as to the cause of their death. The tops were comparatively fresh and green, but the roots were brown and rotten, and a few inquiries left no doubt that frost had got into the frame and done the damage. Of course, a fairly severe frost would be required, but we got several such last year.—E. J. K.

Sweet Peas.

When growing Sweet Peas grow only the best. A superb display occupies no more space, takes no more time to cultivate, neither does it cost any more than a poor show.

To obtain the very best send direct to Eckford for your seeds; **but remember they are only genuine when obtained direct from Wem.**

1908 NOVELTIES.

There are 11 distinct novelties or 1908, and are offered to the public at 1s. per packet each. Full particulars are given in Catalogue, *also details of some very special offers.*

SPECIAL NOVELTY OFFER.

One packet of each of the eleven Grand 1908 Novelties for 9s. 6d. post free; half packet of each, 5s., post free for cash with order.

A Booklet, giving Full Particulars on the Culture of Sweet Peas, given with every order.

FREE. Send a postcard for Coloured Illustrated and full descriptive Catalogue. It is sent post free. Write to-day.

WALLACE'S

MAY-FLOWERING COTTAGE AND DARWIN

TULIPS

have received highest honours from the Royal Horticultural Society for several seasons.

As a means of helping those who are unacquainted with the many varieties of Tulips we have selected six of the finest and most interesting from the May-flowering race, and offer them at a specially low rate. All are first-class sorts of great garden value that have received certificates.

FLAME, fiery scarlet. **THE FAWN,** fawn and apricot.
LEGHORN BONNET, straw yellow. **MRS. MOON,** clear yellow.
INGLESCOMBE PINK, strawberry pink.
INGLESCOMBE SCARLET, scarlet.

Ten each of the above choice varieties, 60 bulbs in all, for **15/-**. Twice the quantity for **27/6.**

Gold Medals, Hardy Plants, Temple Show, 1903 to 1907. Unique record.—Lilies, Calochorti Iris, Eremurus (raised by the late Sir M. Foster), Montbretias (Davison's seedlings), Tritomas, Bulbous, Alpine, and Herbaceous Plants in endless variety. Catalogue free.

NOTES OF THE WEEK.

Nitrogen.

It is a very curious fact that while our atmosphere contains two gases which are essential to plant life, viz., nitrogen and carbonic acid, the former forming the major part of it and the latter an extremely small one — only about the three-thousandth part—it is only this latter which is utilised by direct absorption by the leaves from the air. The two gases, however, are of very different nature, nitrogen being a simple elementary gas, i.e., not an admixture, while carbonic acid is a mixture or compound of oxygen, the other chief atmospheric constituent, and carbon which normally is a solid body assuming several forms even in its pure state, the brilliant diamond and the black opaque coal forming examples of its diversity. It is doubtless due to this compound nature, which involves a capability of dissociation, that plants are able to break it up and utilise the carbon element as building material, while nitrogen can only be utilised indirectly. Until quite recently it was assumed that this element could only be introduced by means of nitrogenous manures of various kinds, that is, manures containing earthy salts in combination with nitrogen, the plants then possessing the power of assimilating what they required. The fact, however, that these nitrogenous substances though plentiful enough in some parts of the world, such as the nitrate districts of Iquique, South America, were fairly costly owing to expense of transport, etc., while all the time the plants were literally bathing in the essential gas itself, has led to many experiments in the direction of a more direct supply. Such supply, however, had so far been found impracticable by man on commercial lines, until it transpired that there were certain natural agencies open to him, both able and willing to do the work well and thoroughly if given a little encouragement. It is a matter of tradition, as well as practical experience, that crops of the great pea family, such as clover, peas, beans, etc., differed materially from other crops, since instead of impoverishing the land upon which they were grown they actually enriched it, so that crops of different genera benefited greatly when subsequently grown in the same soil. Careful investigation showed that the roots of these clovers, etc., besides the usual fibrous growths, were studded with little knobs resembling small tubers, but not gifted like tubers proper with the power of reproduction by buds. Further investigation showed that these knobs were invariably tenanted by certain species of miscroscopic bacteria, extremely minute organisms, and some of these being extracted and cultivated by themselves, it was then discovered that they were really the cause of such knobs appearing, and that they in some inscrutable way were able to utilise the nitrogen in the air and give it to the plants, thus stimulating growth to a remarkable extent. It was even found that it was only necessary to wet the seed with water containing these organisms, or their germs, in order to ensure their presence when the seed germinated; and that when infected seed and non-infected seed were sown under precisely similar conditions the infected plants were far and away stronger and robuster than the non-infected ones. This was not all; when infected clover seed was sown with non-infected oats, the crop of oats was finer and heavier than those grown without such association, the benefits of the bacteria extending beyond the clover itself. Professor Bottomley, of King's College, has been following up this line of research for some time, distributing the bacterial germs gratis to a large number of agriculturists and others, the general result being great increase of crops, 70 per cent. in some cases, while the cost of infectious material is very small indeed, and the operation a simple one. Professor Bottomley has recently issued a pamphlet giving full details, including the results of the experiments in question, which both agriculturists and horticulturists should study, since this line of research has revealed a practically inexhaustible source of wealth in the way of increased food supplies, and also in the direction of utilisation of immense areas of now waste land, which it has been proved becomes extremely fertile if these beneficial bacteria be introduced in conjunction with very varied crops.

MR. GEORGE SCHNEIDER.
President of the French Horticultural Society of London.

Mr. George Schneider.—The occasion of the annual banquet of the French Horticultural Society of London affords an excellent opportunity for presenting our readers with a portrait of its worthy and highly esteemed president; and of this opportunity we have much pleasure in taking advantage. For many years Mr. Schneider occupied an important position in the nurseries of Messrs. James Veitch and Sons, at Chelsea, and during that period he had exceptional opportunities for becoming acquainted with the difficulties that beset young foreigners who came to this country for the purpose of becoming acquainted with British horticulture. With a due appreciation of these difficulties he became filled with a desire to take such steps as would lessen them as far as possible, if not to wholly remove them. To give practical effect to this desire Mr. Schneider set himself the task, some twenty years or so ago, of founding a society in London that would form a common ground of meeting for the young gardeners and other horticulturists coming to this country from the Continent of Europe. Such society was formed, and so sound was the basis on which it was established that it has annually increased in strength, and has accomplished an immense amount of useful work. Although designated the Société Française d'Horticulture de Londres, it is by no means limited to Frenchmen. Horticulturists of all nationalities are heartily welcomed as members, and as evidence of the cosmopolitan character of the society it may be mentioned that M. L. Gentile, the able Belgian horticulturist who founded "La Tribune Horticole," and is its editor, was for some time the secretary. The society not only aims at bringing young foreign horticulturists into touch with each other by means of its monthly meetings, but it assists them with advice and also helps them to obtain situations in nurseries, market establishments, etc. Nor is this all, young English gardeners going abroad receive similar assistance. To found a society of this description, and to carry it on successfully for a period of twenty years, represents an amount of energy and sustained effort that is not given to everyone. The task must have been arduous and incessant, but it has certainly had no depressing influence upon Mr. Schneider, who appears never so happy as when among his young friends. It is gratifying to be able to record the fact that his work in the interest of young horticulturists is highly appreciated, both by those who directly benefit from it, and those who are in a position to appreciate its importance. Some years ago, in recognition of his services, Mr. Schneider had the distinction conferred upon him of being made by the French Government a Chevalier of the Mérité Agricole, and, last autumn, he was promoted to the rank of officer of the Order. As an expression of their approval of the well-deserved honour done to Mr. Schneider, the leading French horticulturists entertained him at a banquet and presented him with a handsome testimonial, and a few weeks later a similar compliment was paid him in London. Mr. Schneider, who is a Frenchman by birth, has written the best book about ferns in the English language, and is remarkable not less for his geniality than for his ability.

Horsham Gardens.—As briefly announced in our issue of the 11th inst., we shall describe and illustrate in the GARDENERS' MAGAZINE for February 8 and 15 some of the more noteworthy of the many interesting gardens in the Horsham district. Among the gardens that will be described and illustrated are those of Leonardslee, Denne Park, Warnham Court, South Lodge, Holbrook Park, Wymblehurst, and Warnham Lodge.

Fruit Imports in 1907 exceeded in value by £349,803 those of the previous year, and afforded further proof of the steadily increasing dependence of British markets on the products of foreign orchards for their supplies of fruit. The imports of apples during the year were surprisingly large, amounting as they did to the total of 3,526,313 cwt., of the value of £2,231,327, an increase in value of about half a million sterling, as compared with 1906. In 1906 the imports of apricots and peaches were 7,646 cwt., of the value of £17,967, but last year they amounted in the aggregate to 38,814 cwt., of the value of £78,583. Bananas were received in rather smaller quantities, the aggregate having been 6,232,188 bunches, of the value of £1,771,095. The imports of cherries were smaller than for several years past, the total being 165,412 cwt., of the value of £199,489. Currants, on the other hand, show a, comparatively speaking, small increase. The total imports were 109,130 cwt., of the value of £142,245. Gooseberries were also received in increased quantities, the aggregate having been 45,603 cwt., of the value of £25,994. In the imports of grapes there was a big increase, the total having been 798,377 cwt., of the value of £769,301, against 690,371 cwt., of the value of £667,969. A considerable proportion of this increase was due to the largely increased quantities received in December last. With the imports of oranges, lemons, and nuts we are not specially concerned, but as showing the important position occupied by oranges in the foreign fruit supplies, it may be mentioned that the value of the imports of these fruits last year was £2,454,569. In the imports of both pears and plums there were substantial drops, the most marked decrease being in those of the last-named. The aggregate of the pear imports was 500,142 cwt., of the value of £478,611, and of the plums 325,761 cwt., of the value of £345,720. Strawberries also were received in smaller quantities, the total having been 44,178 cwt., of the value of £54,186. Of unenumerated fruits 538,465 cwt. were imported, and their value was £339,465. The total value of the fruit imports for the year was £10,722,323, a by no means insignificant sum for this country to pay for foreign fruit.

Mr. P. Murray Thomson has so long occupied the dual position of secretary and treasurer of the Royal Caledonian Horticultural Society, and has, moreover, discharged the duties of his offices with so high a degree of ability and urbanity, that it is somewhat of a shock to learn that he has retired from the management of the society. Having experienced much courtesy and kindness from Mr. Murray Thomson we greatly regret his retirement, as do all who have been associated with him in the management of the society. Mr. Murray Thomson is leaving Edinburgh to enter on the position of estate agent to Mr. Parkin Moore in Cumberland.

Gardeners' Royal Benevolent Institution.—The sixty-eighth annual general meeting of this institution will be held at "Simpson's," Strand, on Thursday next, the 23rd inst., at 2.15 p.m. The chair will be taken by Mr. Harry J. Veitch, V.M.H., treasurer. There will be an election of eighteen pensioners on the funds. The poll will be open at 3 p.m., and close at 4 p.m. The friendly dinner will as usual take place in the evening at "Simpson's," commencing at six o'clock. Mr. Martin H. F. Sutton will preside.

Ironmongers' Almshouses in Shoreditch.—We learn from the "City Press" that probably the almshouses in Kingsland Road, Shoreditch, will shortly disappear, and the site be used for building purposes. In one sense the removal of the almshouses, with their old-world appearance and surrounding gardens will be a great loss, but the site is valuable, and doubtless new almshouses will be erected where there will be ample gardens, purer air, and brighter light. One old record dealing with these almshouses is as follows: "1719. The company agreed with Mr. Longstaffe to plant lyme trees in the almshouses, about 80 in number, at 1s. 6d. each, free of all charges, ten feet high at least, and in girth about the bigness of Mr. Longstaffe's legge, in ye small part thereof, any falling within a year to be replaced." We may add that old Sir Robert Geffery, the Cornishman, whose generosity built and endowed the almshouses was one time Lord Mayor of London, and he did many kindly acts, the value of which is by no means exhausted.

The National Chrysanthemum Society will hold its exhibitions during the present year at the Crystal Palace on October 7 and 8, November 7 and 8, and December 2 and 3. The annual meeting will take place at Carr's Restaurant, Strand, W.C., on February 3.

Vegetables of Foreign Growth were imported in largely increased quantities during last year, and the amount that has had to be paid foreign cultivators for their produce has been a large one. The potato imports aggregated 8,249,463 cwt., of the value of £2,371,617, against 3,819,787 cwt., of the value of £1,332,027, in 1906. Of the immense quantities imported last year 88,264 cwt. came from Germany; 119,351 cwt. from France; 291 cwt. from the Channel Islands; and 231,927 cwt. came from "other countries." Their near relatives the tomatoes were also received in enormous quantities last year, the total imports aggregating 1,135,594 cwt., of the value of £1,020,795. The imports of onions also evince a material increase, the total having been 8,645,048 cwt., of the value of £1,036,231. Unenumerated vegetables were an exception to the general rule, inasmuch as they show a considerable decline in value, as compared with both 1906 and 1905. The value of the vegetable imports was £4,793,893, making with the amount paid for fruits a total exceeding fifteen and a half millions paid during 1907 to foreign cultivators for fruits and vegetables.

R.H.S. Exhibitions in 1907.—At the afternoon meeting of the Royal Horticultural Society on Tuesday Mr. J. Gregory gave a very interesting lecture, illustrated with lantern slides, on the more important of the contributions to the society's exhibitions during last year. Plants, fruits, flowers, and vegetables were included in the slides thrown on the screen, and as much judgment had been exercised in the selection of subjects, the series proved highly entertaining to the audience.

Kew Seed List.—We have just received a copy of the "List of Seeds of Hardy Herbaceous Plants, and of Trees and Shrubs," published by the Kew authorities. This list is for circulation among Kew correspondents, and shows what seeds, ripened at Kew, are available for exchange with Botanic Gardens, etc. The list runs to twenty-one pages and begins with Acæna macrostemon and finishes with Zenobia speciosa var. pulverulenta.

Brighton and Sussex Horticultural Society has sustained a loss of £16 12s. 4d. on the recent year's working. This is not welcome news. The exhibitions have been better than usual, and the loss on them much smaller than usual, but the deficit on the year's account is chiefly due to a falling off of subscriptions. The annual meeting is to be held as we go to press (Thursday), and we hope the prospects for 1908 will prove brighter than the result of 1907. Fortunately the society has accumulated a fair balance in bygone years, and has nearly £250 to start the year with; the general account shows a turnover of £1,150 15s. 9d.

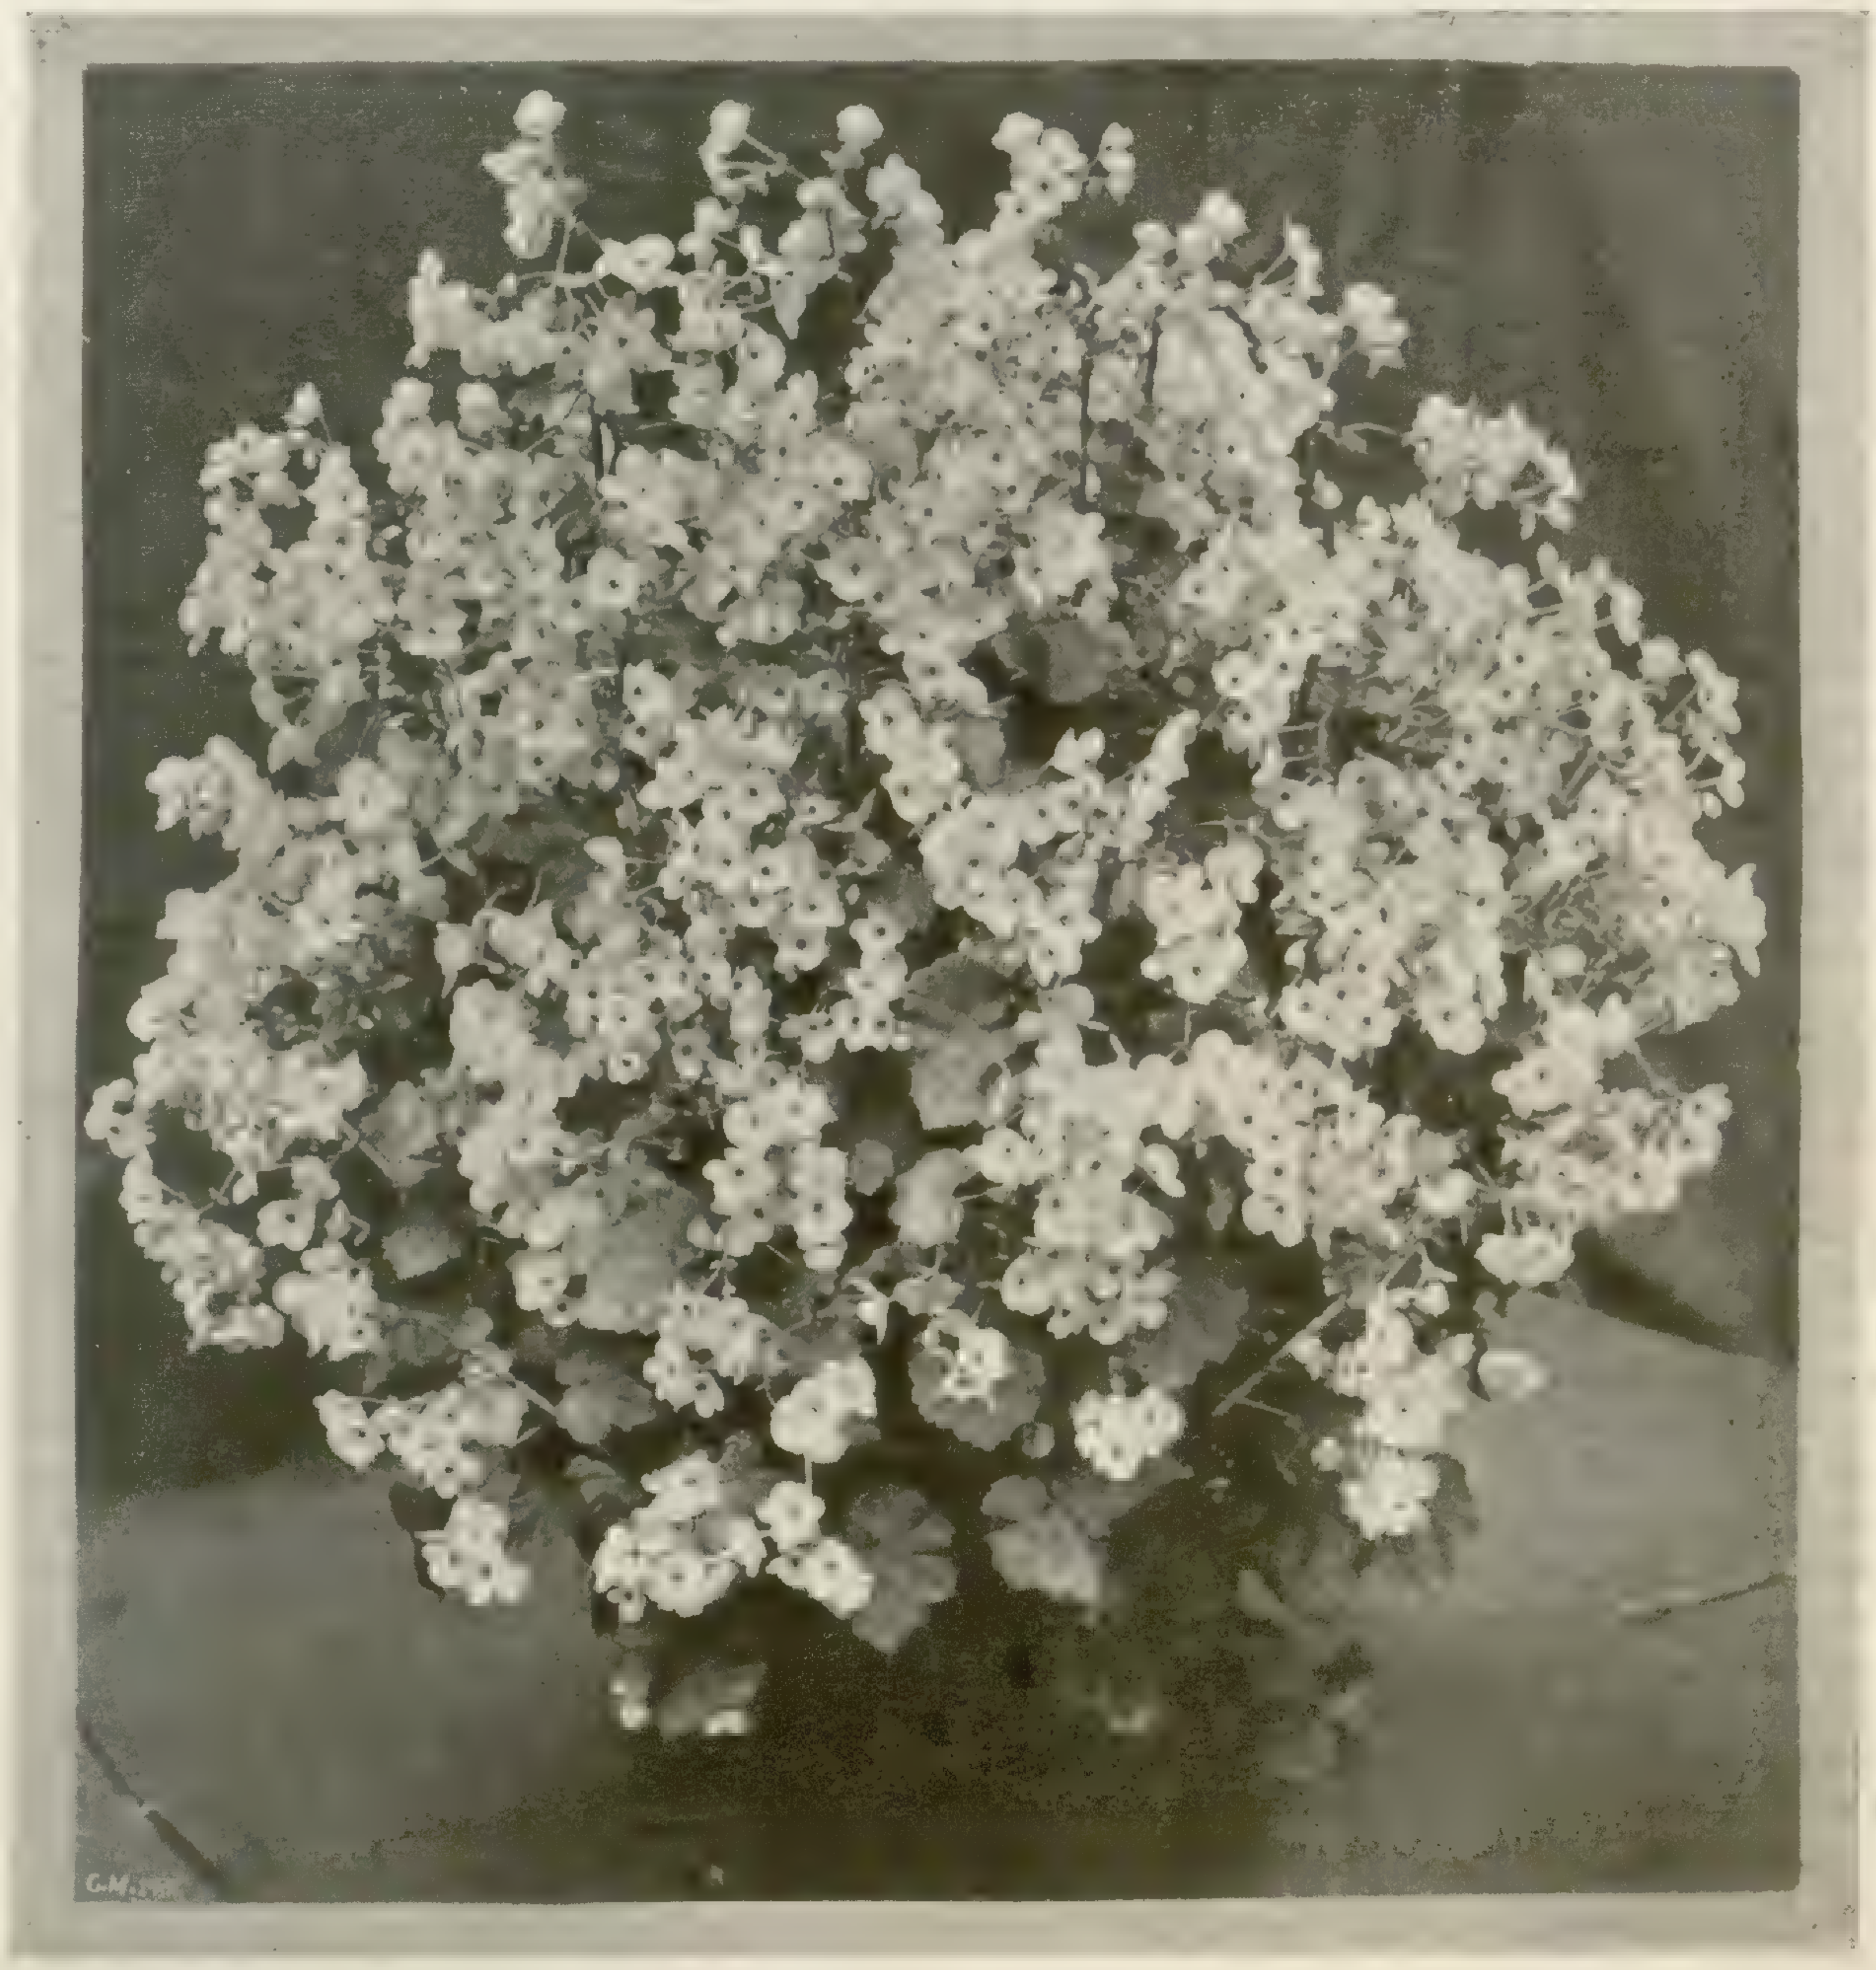
Gosport Gardeners' Association continues to make good progress, and has become so well established that this year it will hold monthly meetings, at which papers will be read, and two exhibitions. The date of the summer show is July 8, and that of the autumn show has yet to be fixed. The programme of the monthly meetings is as follows: February 5, "Potatoes"; March 4, "Outdoor Mushroom Culture"; and April 1, "Construction of Glass Houses," by Mr. C. F. Laurence, Hants County Council lecturer; May 6, "Hints on Hardy Fruit Culture," Mr. J. B. Groom; June 3, "Roses," Dr. Lamplough; July 1, "Origin and Composition of Soils," Mr. G. E. Smith, B.Sc.; August 5, "The Storing of Fruit," Mr. T. Naish; September 2, "Culture of Fruits under Glass," Mr. J. Dawe; October 7, "Bulbs," Major G. Churcher; November 4, "A Gardener's Pot-Pourri," Captain G. A. Broad, M.V.O.; December 2, Annual Meeting; and January 6, 1909, "Primulas," Mr. C. Coleman.

Disfigurement of Rural Scenery.—Lovers of the amenities in the rural districts of England have, since the advent of the motor car, had plenty to try their patience, and to cause them much regret. They have seen gardens and hedgerows covered with dust in consequence of the rate of speed at which the majority of motor cars travel, and now they find rural districts disfigured by advertisements of motor cars, and their accessories. In a letter to the "Times" with reference to this objectionable procedure, Mr. W. D. Caroe writes: "More and more frequently the approaches to the smaller provincial towns, and even to the villages, are being placarded with motor advertisements, disfiguring too often charming old cottages or barns, and destroying characteristic rural scenery. . . . . . We are already too familiar with the plague of pill and lotion puffs and posters, which, along the path of the railway, constitutes so grave a reflection upon the nation's good sense and taste. These at least obtrude themselves more upon the rapid traveller than upon the country pedestrian or anyone else. But the new form of the disease threatens the country dweller in his most frequented and legitimate haunts, and, if allowed to flourish, as competitive vulgarities will, the charms of our country roadsides are destined soon to be doomed. With the rapid spread of our towns in area and hideousness, every rural district left undefiled becomes more precious to the country at large—more precious specially to the town dweller—most precious, one might have thought, to the motorist, with all his newly-got opportunities of visiting it. The carriage builders, horse dealers, and blacksmiths of the age of horse traction did not find it necessary thus to defile the countryside. Why now the motor dealers?" Being in full sympathy with Mr. Caroe we trust he will receive the support for which he appeals, in so good a cause as "the keeping sweet and undefiled of rural England from uncalled for and misplaced disfigurement."

Production of Attar of Roses.—According to the report of M. Max Choublier, the French Consul at Philippopolis, the manufacture of attar of roses continues to be one of the principal industries in Eastern Roumania. During the past twenty-five years the industry has shown a steady increase. In 1884 the production of attar and rose water was 81 kilogrammes (1 kilogramme = 2.2055lb.), and in 1905 the quantity of attar alone was 5,316 kilogrammes.

BEGONIA GLOIRE DE LORRAINE.

During the past few years it has been our good fortune to see many finely grown examples of the beautiful and extremely useful Begonia Gloire de Lorraine and its varieties. Sometimes they have been bush specimens of large dimensions, at others they have been of a size suitable for decorative purposes in the drawing-room and other indoor apartments, and in some instances they have occupied suspended baskets and overshadowed the plants on the stages below with huge clouds of their exquisitely coloured flowers. We have a clear recollection of the finest of these, so pleasing was the impression they produced, but we are wholly unable to call to mind any that were superior to the magnificent specimens that have formed such a glorious feature of the Audley End gardens during the current winter. Examples of different sizes were grown, and all were remarkable for their flower production and finish. Some of the larger specimens were contributed by Mr. James Vert, the able chief of these gardens, to the meeting of the Royal Horticultural Society held on November 26 last, when they were much admired, both for the skilful culture they displayed and for the taste evinced in their arrangement. Sufficient specimens were exhibited to fill a broad table extending one-half the length of the Horticultural Hall, and they were set in a ground work of ferns just high enough to hide the pots. The specimens included Gloire de Lorraine, and its two fine varieties, Mrs. Leopold de Rothschild and Turnford Hall. We illustrate herewith the first of these two varieties which has bright pink flowers of comparatively large size. Turnford Hall has white flowers, and is of much value for its distinctness.



A FINELY FLOWERED SPECIMEN OF BEGONIA MRS. LEOPOLD DE ROTHSCHILD, GROWN AT AUDLEY END.

Flowers bright pink.

Mr. J. Vert has kindly contributed the following notes on the practice by which he has obtained such splendid results.

With reference to the cultivation of winter-flowering begonias of the Gloire de Lorraine type, I would say that to ensure the production of good examples healthy cuttings are essential. The cuttings should be inserted at the beginning of March in thumb-pots, using a compost consisting of two parts of loam, two of leaf-mould, and one of silver sand. As the cuttings are inserted plunge the pots in a propagating case at a temperature of 70 degrees. They will be nicely rooted in about a month.

When the plants are rooted, gradually inure them to the atmospheric conditions of the structure in which the propagating frame is placed, and transfer them to large 60's, using a compost prepared as advised above. Keep the plants growing with the aid of a moist atmosphere and a temperature ranging from 60 to 65 degrees, spraying them over once or twice a day and shading from bright sunshine are essential to success; shift them on as required. Good plants for general decoration may be had in 48's and 32's, but larger plants for specimens should be shifted into 24's. Grown in baskets suspended from the roof they are most effective when in bloom, and useful both for the conservatory and mansion. Well grown basket specimens will form a mass of flower five feet in diameter are extremely beautiful.

As the pots become filled with roots frequent applications of liquid manure will prove beneficial in promoting a sustained and vigorous growth. Remove all flowers as they appear until about six weeks previous to the time the plants are wanted at their best.

I would add that attention to details is necessary throughout the whole period of growth, but this is amply repaid by the brilliant display of colour that will be produced from October to March at a period of the year when generally speaking flowers are scarce. JAMES VERT.

Audley End Gardens.

FAILURES IN FRUIT CULTURE

Almost every practical gardener is asked the frequent question, why does not such and such a tree bear fruit? Very often this and similar questions come from some bewildered amateur, or the owner of some small garden, whose trees either fail to grow satisfactorily, or after they have grown fail to carry a crop of fruit. There are, I think, two causes why such conditions prevail, and they may be classed as preventable, and nonpreventable. With the latter case possibly it is beyond human aid to make it successful in all cases, as a bad climate and bleak situation would prove. Unfavourable soils may be improved by so adding to or taking away, as to make the staple capable of yielding successful results. But in the majority of cases these failures are traceable to

Preventable Causes.

I have in my mind's eye a striking example of a failure in recognising the importance of beginning well. The trees, as is the case in many instances, were purchased at auction in the cattle market. They are as a rule the outcast or clearing up of the nurserymen's season, but it is not the practice of all the members of the trade to dispose of their clearings up in this way. On the contrary, many of the nurserymen in finally clearing the quarters dispose of the remnants by burning. The trees in question the longer they remain, the more worthless will they become, possibly a few may struggle on and form trees, but miserable specimens they will be, and I need hardly say that prematurely old, stunted trees and bushes are dear at a gift.

If the expenditure of the planter must be limited, it is more economical and wise to purchase young maiden trees. Much time is gained by planting good-shaped well-grown trees, and they are in every way more satisfactory. Sometimes we are met with the remark: See what fruit these grotesque, ill-shapen old trees produce; but although such trees do bear crops it does not necessarily follow that the best way to secure fruitful trees is to plant those which are ill-shapen and deformed.

Unsatisfactory Planting.

I have often discovered that bad planting is another cause of failure, nothing turns young trees into prematurely old ones sooner; they never have a chance of recovering from the time they are planted. I must also especially refer to the objectionable practice of digging out holes just large enough to hold the roots, and this frequently in land of a hard, retentive, clayey nature, which has not been broken up or trenched. I can best show the objection to this practice by comparing it with cramming the roots into a large flower pot. The roots under such circumstance do not strike out readily into the soil in search of food. When the conditions that prevail make it necessary to plant in soil that is more or less unsatisfactory, a hole sufficiently large in diameter to allow a free growth of the roots without check must be made.

Filling-up Gaps in Orchards.

Another great mistake that occurs in the case of both landowners and tenants is the practice of filling up gaps in orchards. It is stipulated in some leases of farms containing an orchard, that gaps in them shall be filled up as they occur, consequently generation after generation that is done with the same kind of tree. All practical workers of the land regard the annual rotation of ordinary farm crops as of the utmost value, therefore it should be readily seen that a change is necessary where fruit trees have been grown for a generation.

Pruning.

This has to answer for many failures, and in most cases through the operators not following a middle course. Extension is advocated by some, and if carried out in its entirety, resolves itself into letting the trees alone. Some who do not obtain the extra labour required in careful pruning are partisans of it, until the system does not give the desired results. Then not only are the pruning knife and hook requisitioned, but the saw is made vigorous use of. More than one instance has come under my direct notice where whole cartloads of wood have been cut from the trees at one time, and in consequence the trees have ben so paralysed by the shock that several years have passed before they fully recover. In some cases the trees were only fit to be grubbed up. Pruning is decidedly beneficial if performed at the right time, and in the right manner. With orchard trees this should be done annually, and with trained and other forms of trees twice yearly is necessary. To allow trees to run wild for five or six years and then cut away six times as much wood as ought to be cut out at one time, is a direct road to failure. Another source of failure, and perhaps not the least, is injudicious selection of varieties.

This is often brought about by the cultivator admiring certain varieties at the fruit shows, noting them down, and then, without any knowledge of their peculiarities, planting them. This mistake more frequently occurs with pears than apples. These are most exacting as to districts and soils, and some knowledge must be obtained of them before planting to ensure success. There are, however, many good standard kinds of fruits that can be planted with confidence. The foregoing are a few of several causes of failure in fruit culture, but with a little forethought and advice they may be averted. W. H. CLARKE.

Aston Rowant Gardens.

American Gooseberry Mildew.—What an obliging institution the Board of Agriculture is, to be sure! Some time ago it set out to eradicate American gooseberry mildew by issuing an order that all affected bushes should be destroyed, but somehow gooseberry growers did not quite see the force of their means of livelihood going up into the air in smoke without some compensation, which county authorities did not see their way to give, so they not unnaturally resented the order. A deputation to the Board followed, and, instead of wholesale destruction, affected bushes are now to be pruned and sprayed. Probably those law-abiding citizens who burnt their bushes under the original order now wish they hadn't, and the change of tactics is very puzzling to the man in the street, who hears from one expert that destruction is the only means of eradicating the disease, and from another that such a contention is absurd, as it can be dealt with effectually by measures much less drastic.—SPY.

ZYGADENUS ELEGANS.

There is much to admire in this very quaint and pretty bulb from North America, one of a group collectively called fly poison—a name rightfully belonging to Z. muscitosicum, but loosely applied to all the zygadenus, at home and in America. It has glaucous leaves in loose rosettes that resemble tuberoses in habit, and in summer it throws up a very pretty panicle of flowers that are coloured a quaint shade of silver-grey, striped as in Ornithogalum narbonense, and literally produced in hundreds. The panicle is exceedingly loose, and in this respect gains in elegance, its height being two to three feet, and it lasts six weeks in full flower.

This zygadenus is one of many American bulbs that should prove more satisfactory garden plants than those we have received in quantity already from that Continent. I have tested its hardiness often and have not lost a single plant through frosts. It will grow in any good soil, but prefers a damp sandy loam. I have seen splendid examples in the red loam of a Somersetshire garden, taller and stronger than I could grow in a poor soil near London. In the south-west it should prove most delightful, as it can withstand the moist climate and appreciate the sunshine, and in Devon, Cornwall, Ireland, and the North-west of Scotland, it will probably surpass its best efforts elsewhere.

These rare bulbs add interest to any garden, and when they come to us without cultural disabilities we can welcome them the more, particularly when their flowers are novel and artistic, and elegant enough to have won a desirable specific name.

G. B. MALLETT.

WINTER-FLOWERING SWEET PEAS.

The new race of winter-flowering sweet peas, which originated in the United States, have already been taken in hand by several growers, and the results seem to point to a bright future for this section of the sweet pea.

Notes of a recent trial of some of these varieties at the Ramee Nurseries, Guernsey, provide not only interesting reading, but also matter for reflection to the many gardeners who have to provide plenty of cut flowers during the dull months of the year. The varieties in question were sown in the early days of October, and began to expand their blossoms during the last week of November. Quick work, you will say, and from the accounts given, the trial was mainly to see how soon they could be brought into bloom. It was particularly observed that the lilac, mauve, and purple shades were the first to blossom. The sweet peas in the case in question were forced in a temperature of 60 deg., though, had the growers been content with, say, 50 deg., they would have undoubtedly secured better flowers, though, of course, they would have been several days later. The varieties ranged in height from three to four feet, not a bad height at all for ordinary requirements, but I believe that some of the New Jersey seedlings of Mr. L. Volanek attain a much greater height than this. On the other hand, the scarlet variety Early Bird, and the primrose Sunbeam, and a few others are dwarfer than the ordinary forms. With careful selection and intercrossing, the best of the varieties at present in commerce may be rapidly improved, in which case the new race of sweet peas will prove a valuable asset in the hands of both the market grower and the private gardener, for the sweet pea is such a favourite flower that the opportunities of having them in flower during the winter will be made full use of, especially as they are so useful for decorative purposes. P. S. HAYWARD.

THE BUDDLEIAS.

Recent introductions from China have caused the genus Buddleia to advance rapidly in public favour during the last few years, for several of the newer species and varieties are of considerable decorative value, and are of such easy culture that the merest novice need not anticipate failure. Altogether there are about a dozen species in cultivation, and, with the exception of three, they can be cultivated in the open ground in the neighbourhood of London and south and westward, receiving little or no injury from frost, except during an exceptionally severe winter. These species are very widely distributed, some being found in South Africa, others in China, Japan, Sikkim, Chili, and Peru, etc.

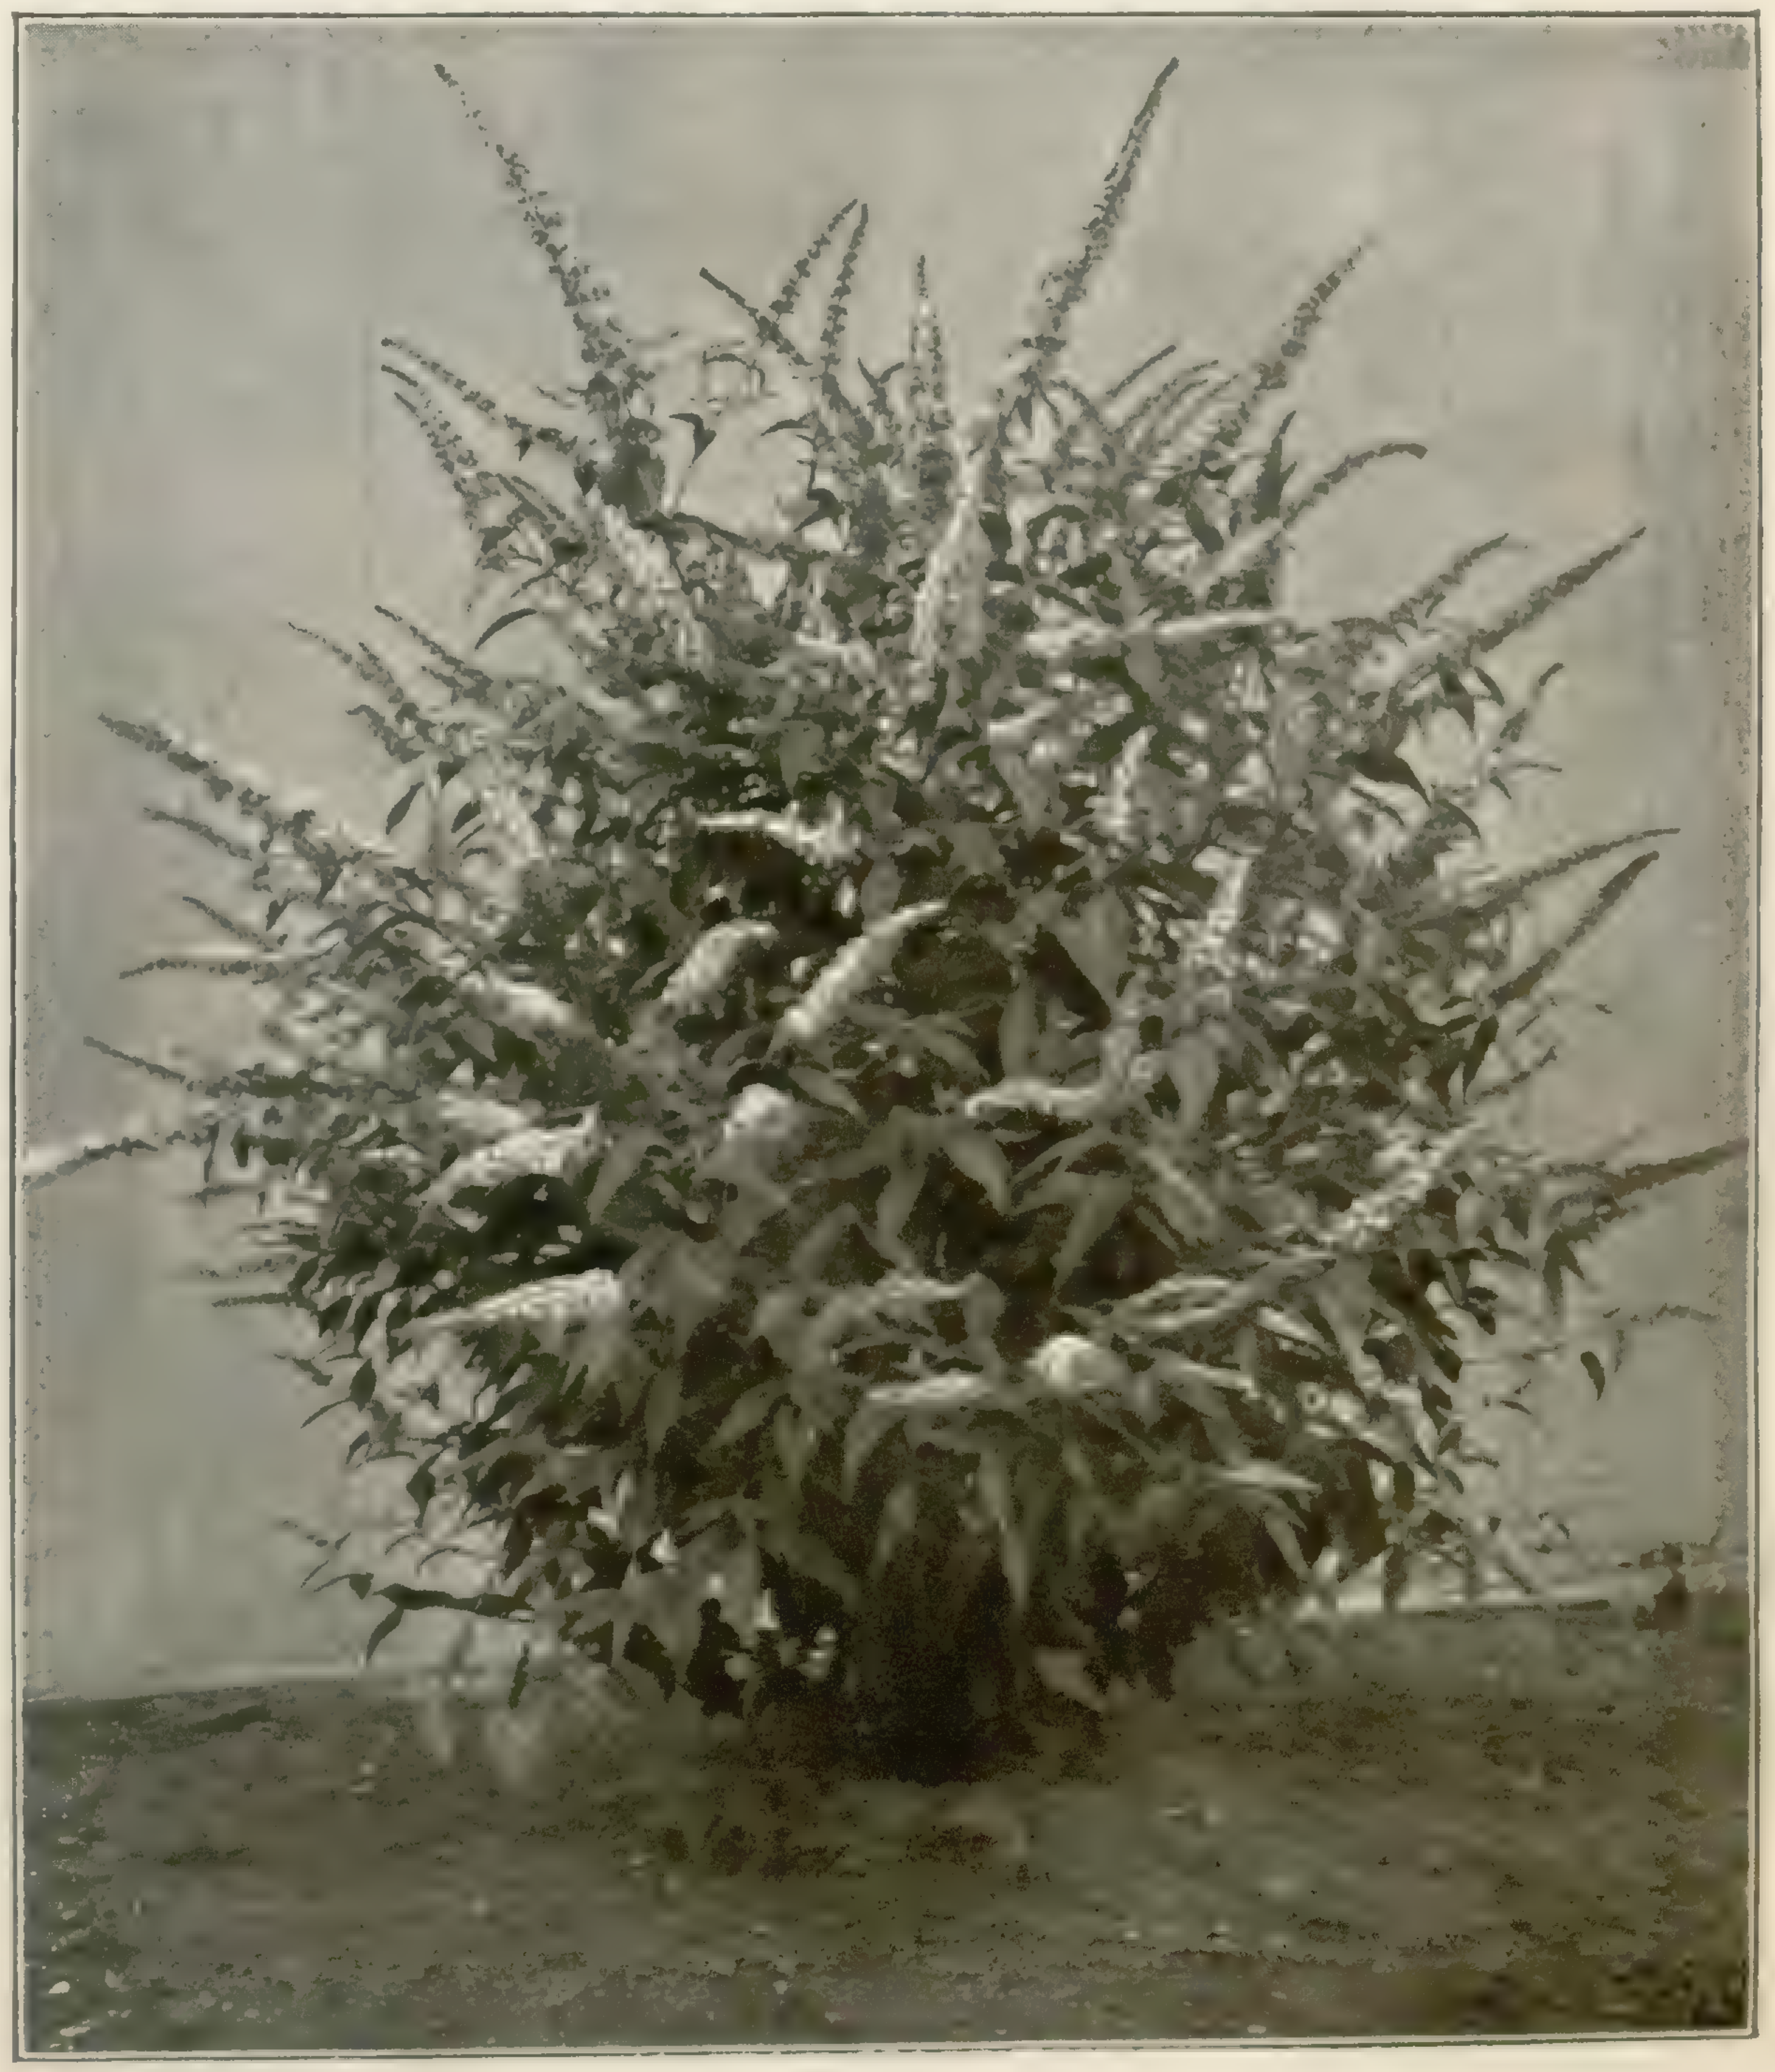
Although one or two species have rather ornamental foliage, it is as flowering plants that they are grown, and the majority of them are exceedingly floriferous and fragrant. In the open ground in the southern counties they rapidly form huge bushes, while in cold districts, if planted against a south or west wall, they quickly cover a large area, and are very ornamental when allowed to hang loosely from their support, the main branches only being secured. Though some sorts, such as B. globosa, thrive and flower well in poor, sandy soil, others, particularly the variabilis set, require very rich loamy soil to attain a high degree of excellence. When preparing ground for them it should be trenched two feet deep and well manured, and if very poor good loam should be added. Quite small plants may be placed three feet to four feet apart, if to be grown in a mass, and these, in a very short period, will meet. Single plants of the variabilis set, however, such as is shown in the accompanying illustration, are very appropriate, especially as lawn specimens, as they form well-balanced bushes with very little attention. The principal end to aim at in the cultivation of the variabilis varieties is the production of strong, sturdy shoots capable of bearing large inflorescences. To effect this end, it is necessary to commence in spring, say early March, by cutting the plants well back to within a bud or two of the base of the last year's wood. At the same time the surface soil should be lightly forked over and a surfacing of rich farmyard manure given. About June, when growth is rapid, an application of liquid manure is productive of good results. Such species as B. Colvillei, B. globosa, and B. paniculata are more satisfactory when allowed to grow naturally into large bushes, sufficient pruning only being done to keep the plants shapely and free from dead wood.

The few tender kinds are suitable for the greenhouse, and thrive in a compost of good fibrous loam, with one-fourth of its bulk of leaf-mould or peat, and sufficient sand to keep the whole open. B. asiatica is worthy of attention from everyone who has to keep a conservatory gay, for it is very floriferous, and lasts in flower for a long period.

Most of the buddleias can be easily increased by means of cuttings of young shoots in summer, whilst several of them set seeds freely, which germinate within a few weeks of sowing. The following represent the species in cultivation:

B. asiatica.—This Asiatic species has been brought prominently into notice of late as a greenhouse flowering plant, though it is by no means of recent introduction, having been introduced into English gardens from India over thirty years ago. It is of rather slender growth, and may be had from three to six feet high, the secondary branches being terminated by long close racemes of small fragrant white flowers. The leaves are lanceolate and very finely toothed. It is a very graceful plant, and well adapted for decorative purposes.

B. auriculata.—A South African plant of slender growth, with broadly lanceolate leaves two inches or so long, pale green above and silvery beneath. The flowers are cream-coloured and small. It requires greenhouse protection, but is of no special value, being of botanical rather than horticultural interest.



BUDDLEIA VARIABILIS VEITCHIANA.
A specimen growing in the Coombe Wood Nurseries. Flowers, lavender blue.

B. Colvillei.—This has been described as probably the most beautiful flowering shrub of the Sikkim Himalaya, and certainly when seen at its best it is a glorious subject. Growing naturally, it forms a bush quite twenty feet high, with ovate-lanceolate leaves six to eight inches long, green above and silvery and pubescent beneath, and terminal panicles twelve to eighteen inches long of red or rose-coloured flowers. These flowers are large, and singularly like a garden pentstemon flower in size and colouring. In the warmer parts of the country it succeeds in the open, but in other places it is necessary to plant it in a cool house.

B. globosa.—Previous to the introduction of the finest varieties of B. variabilis this was the best known of the various species. When mature, specimens are found ten to 20 feet high, and as much through. The young wood is covered with a greyish felt, as also are the undersides of the leaves. The leaves are lanceolate, about six or seven inches long, and evergreen or sub-evergreen. The flowers are orange-coloured, and borne in round ball-like heads, several of which compose an inflorescence, during June. It is very ornamental, and succeeds in most places.

B. intermedia.—This is of hybrid origin, the parents being given as B. curviflora and B. Lindleyana. The former of these two species is not described here, as it is rarely seen in cultivation; there is, however, another curviflora, which is a synonym of japonica. B. intermedia grows about three feet high, and bears ovate-lanceolate leaves and small purple flowers in long slender racemes. It is not very hardy.

B. japonica.—A fast-growing species from Japan, which grows to a height of five or six feet. The branches are curiously winged, and produce oblong acuminate leaves six to ten inches in length. The flowers are deep lilac, half an inch or so long, and borne in dense pendulous racemes, sometimes as much as eighteen inches long. It is very floriferous, the flowering season extending from May to October. This free-flowering propensity has the effect of quickly exhausting the plant, and it requires renewing from seeds every few years.

B. Lindleyana is a species from China and Japan with prominently four-angled, slightly winged stems, thin ovate acuminate leaves, with almost entire margins, and terminal racemes of purplish flowers. It forms a bush four or five feet high, and blossoms freely during autumn.

B. madagascariensis. This is a tender species of slender habit from Madagascar. It requires the protection of a warm greenhouse, and is an excellent plant for covering a tall pillar, rafter, or wall. In the Temperate House at Kew it has been planted against a pillar and carried up a rafter above the gallery, and is now about fifty feet in height. It can, however, be kept within bounds in a small structure by pruning. The branches, undersides of the leaves, and flower stalks are all covered by a dense white pubescence, which adds materially to the effect of the plant. The leaves are ovate, six to eight inches long and two inches wide. The flowers are small, of a rich deep orange shade, fragrant, and borne in elegant branched racemes a foot to eighteen inches long. It blooms profusely during late spring and again in autumn.

B. paniculata.—This is sometimes met with under the name of B. crispa. It is found in Afghanistan, Burma, and China, and is variable in character. The typical form has rather small crisped or wrinkled leaves, which are covered on both sides with a whitish tomentum. The flowers are lilac, with a lighter centre, and borne in small panicles in May and June.

B. pulchella is a native of Natal, and requires indoor culture in this country. It grows about five feet high, and produces small green leaves and cream-coloured flowers. It is not of any decorative value.

B. variabilis.—This is a Chinese plant of considerable decorative worth. If allowed to grow naturally it attains a height of ten or twelve feet, with a wide spread. The leaves are oblong or lanceolate, six to twelve inches long, green above and whitish beneath. The flowers are small, fragrant, lilac-coloured, and borne in dense terminal racemes from every shoot during autumn. Good as the species is, however, it is quite eclipsed by the varieties Veitchiana and magnifica, which have been introduced by the Messrs. Veitch, of Chelsea, through the medium of their collector Mr. Wilson, from China. The former of these two produces racemes of bloom two feet long, whilst those of magnifica are even larger. Both are excellent free-flowering shrubs, and are worthy of extensive cultivation.

B. albiflora and B. Hemsleyana are new Chinese species, introduced by the Messrs. Veitch; they are of the variabilis type. The two species are rather similar in general appearance, but albiflora has more prominently angled stems than Hemsleyana, and the leaves are different in texture and less silvery on the under surface. Both produce very long inflorescences, the flowering time being August. The name albiflora was not happily chosen, for both plants have lilac-purple flowers.

W. DALLIMORE.

Making up Hotbeds.—Gardeners in general have just cause for complaint that they do not obtain enough manure; but there are some folk who get hold of far too much, judging by the appearance of their old hotbeds when the latter are dismantled. When a dismantled hotbed shows a mass of white material near its centre the old practitioner knows at once that hotbed has only been half a success; it has heated violently for a short time, and then settled down to an apathetic coldness. Now, a hotbed should not heat thus spasmodically; it should give out a gentle but long lasting warmth. And to ensure its doing so, the manure employed should be balanced by an equal quantity of dead leaves.—E. J. K.

DRASTIC MEASURES.

The arguments that can be used in favour of drastic measures being undertaken whenever plants are plagued with an abnormal attack of some insect pest, or injured by a fungoid disease, are so strong and so plentiful that it is hard to understand why drastic measures should not figure more prominently as a weapon of war.

By drastic measures is meant, of course, those which have for their object the complete emancipation of the plants and the utter destruction of the pests. This may involve some loss, some sacrifice of plants, but the price is well worth the purchase. Better by far lose a few and be blessed with cleanliness, than have the whole stock continually troubled, and in spite of all cultural ability unable to be raised above the level of mediocrity. This is a state of affairs which too often exists, both with amateurs and professionals.

The wretched policy of "keeping it down," or still worse of "laissez-faire," is one which is painfully prevalent, and should be resisted by all who bear the banner of progress. No single act or established policy has injured the cause of progressive horticulture more than this method of allowing a pest to exist as long as it could be confined within certain limits. It is opposed to progress. It is opposed to economy; and it is in direct antagonism with the dictates of common sense.

How can the best cultural practice prevail in the formation of handsome specimens when the plants are disfigured and their precious sap absorbed by enemies. Undoubtedly it would take some time to effect a lasting clearance. It may even to some extent upset the usual arrangements of labour, but in point of time of labour and of money, taken in the aggregate, it will be found cheaper to deal with the matter thoroughly rather than be continually treating it superficially.

Before proceeding further, by way of precept, it may be well to mention a case which some years since came under my notice. The cattleyas in the place alluded to were troubled with the "fly," which lays its eggs and hatches the young maggots in the roots of the plants. This causes them to swell, and, of course, impairs the action of the roots, and as a certain consequence has a decidedly detrimental effect. Every cattleya brought into the house was in turn attacked, but strange to say, although several other orchids were present the pest with nice discrimination confined its attacks to cattleyas and lælias. Remedies were, of course, discussed and undertaken. Fumigation was found to destroy the fly when on the wing, but was powerless to affect those eggs or maggots which were maturing within the roots. Every visible swollen root was cut off, but by the continued attack of the pest it was apparent that a breeding place must have been found in those roots bedded in the compost. The practice, and supposed remedy, of leaving night-lights in the house to induce some of the flies to undertake self-destruction in the flames was tried for some considerable time, without very satisfactory results. As these remedies had no other effect than to stem the rush of evil, other more drastic measures were planned and undertaken.

Those measures I will describe. The plants were taken from their pots and all the old compost removed and forthwith burnt. The crocks were collected in a tub and the pots put on one side to be washed at the first opportunity. The plants were then taken in hand and every root, young and old, affected or whole, was cut off hard in at the base. All loose matter was pulled off, and the plants were finally washed in strong soapy water with a slight dash of paraffin. They were then forthwith taken to another house which had previously been fumigated to make sure of destroying those flies on the wing. The cattleya house was then thoroughly washed—roof, sides, walls, stagings, pipes, trellis boards, shelves, brackets, wires, and every substance within the house. The ashes on the floor were cleared off and thrown on the common fire. A heavy coat of quicklime was put on the ground beneath, and some sweet clean ashes were brought in. When all was dry a strong fumigation was given as a matter of further precaution.

Meanwhile the cattleyas under treatment were laid out on a staging over a tank and syringed three and sometimes four or five times a day. In less than a week some of them had begun to produce young roots. These were then strung up, roots downward, and still subjected to syringing. When the roots were one inch to one and a-half inches long, the plants were potted up, using peat, sphagnum moss, and charcoal as a compost, and in every case clean new pots and new crocks. In course of time all the plants were potted up, and, although they showed undoubted signs of a check, they soon pulled up with good treatment. The loss did not reach 10 per cent., and I have it on the authority of the gardener now in charge, that after a period of more than five years not a sign of the fly is to be seen, nor has it been known at any time since those drastic measures.

I have another case in my notebook which refers to mealy bug on amaryllis. The attack could by no means be characterised as a moderate one, and the effect on the plants was truly visible. The autumn was chosen for an onslaught on the pest. The plants, which numbered several hundreds, were taken from the pots, the soil was thrown away, and the pots put by to be washed. All loose skins were taken off the bulbs, and all decayed roots were cut away. The bulbs were then washed in an insecticide, and when dry were plunged half-way in shallow boxes of cocoanut fibre and put under a staging where they would not be subjected to water, but could complete their period of rest. As they produced new roots they were in due course potted up. In this case the cure was not wholly complete, for some few of the pests did reappear; but, considering the peculiar structure of the amaryllis, and the lurking powers of mealy bug, there was certainly matter for congratulation in the great reduction of their power, and I doubt not that another such measure would wholly rid the bulbs of them.

On another occasion I well remember we were troubled with brown scale, which was especially noticeable in the stove. As to mealy bug this place was certainly noteworthy in that there was not one on the place. The owner was anxious to get rid of the scale, and for that purpose had recourse to the then almost unknown method of vaporising with cyanide of potassium. The cubical capacity of the house was measured and the amount of cyanide of potassium and sulphuric acid duly purchased. The ventilators were then tightly closed, a basin was put in for the reception of the sulphuric acid and water, and the cyanide of potassium suspended over it in thin paper. A string connected with this paper package was passed along the roof and eventually through the keyhole of the door. When all was ready and the house cleared the cyanide was dropped into the basin. At once there was a process of boiling and the gas was given off. After several hours the doors of the house and the ventilators were thrown open to allow the escape of the gas. As far as the eradication of scale was concerned the result was compeletely satisfactory, but some coleuses were killed, and a few young fronds of adiantums injured. This of course, could not be considered a heavy sacrifice.

Since that time further experiments have increased the efficiency and removed the plant-killing danger of the method. The right quantities of acid, etc., have been more accurately gauged; apparatus has been invented to ensure safety to life in uniting the cyanide with the acid; fans have been arranged for more evenly distributing the gas, and it may now be regarded as a method of pest extermination which only needs practice and publicity.

Drastic measures are sure to meet with the approbation of all reasonable men. To approve a measure, however, is not to adopt it. Gardeners are slow to move, and are most distrustful of any new method, even when it promises complete freedom from some of the most worrying troubles to which plants are subjected.

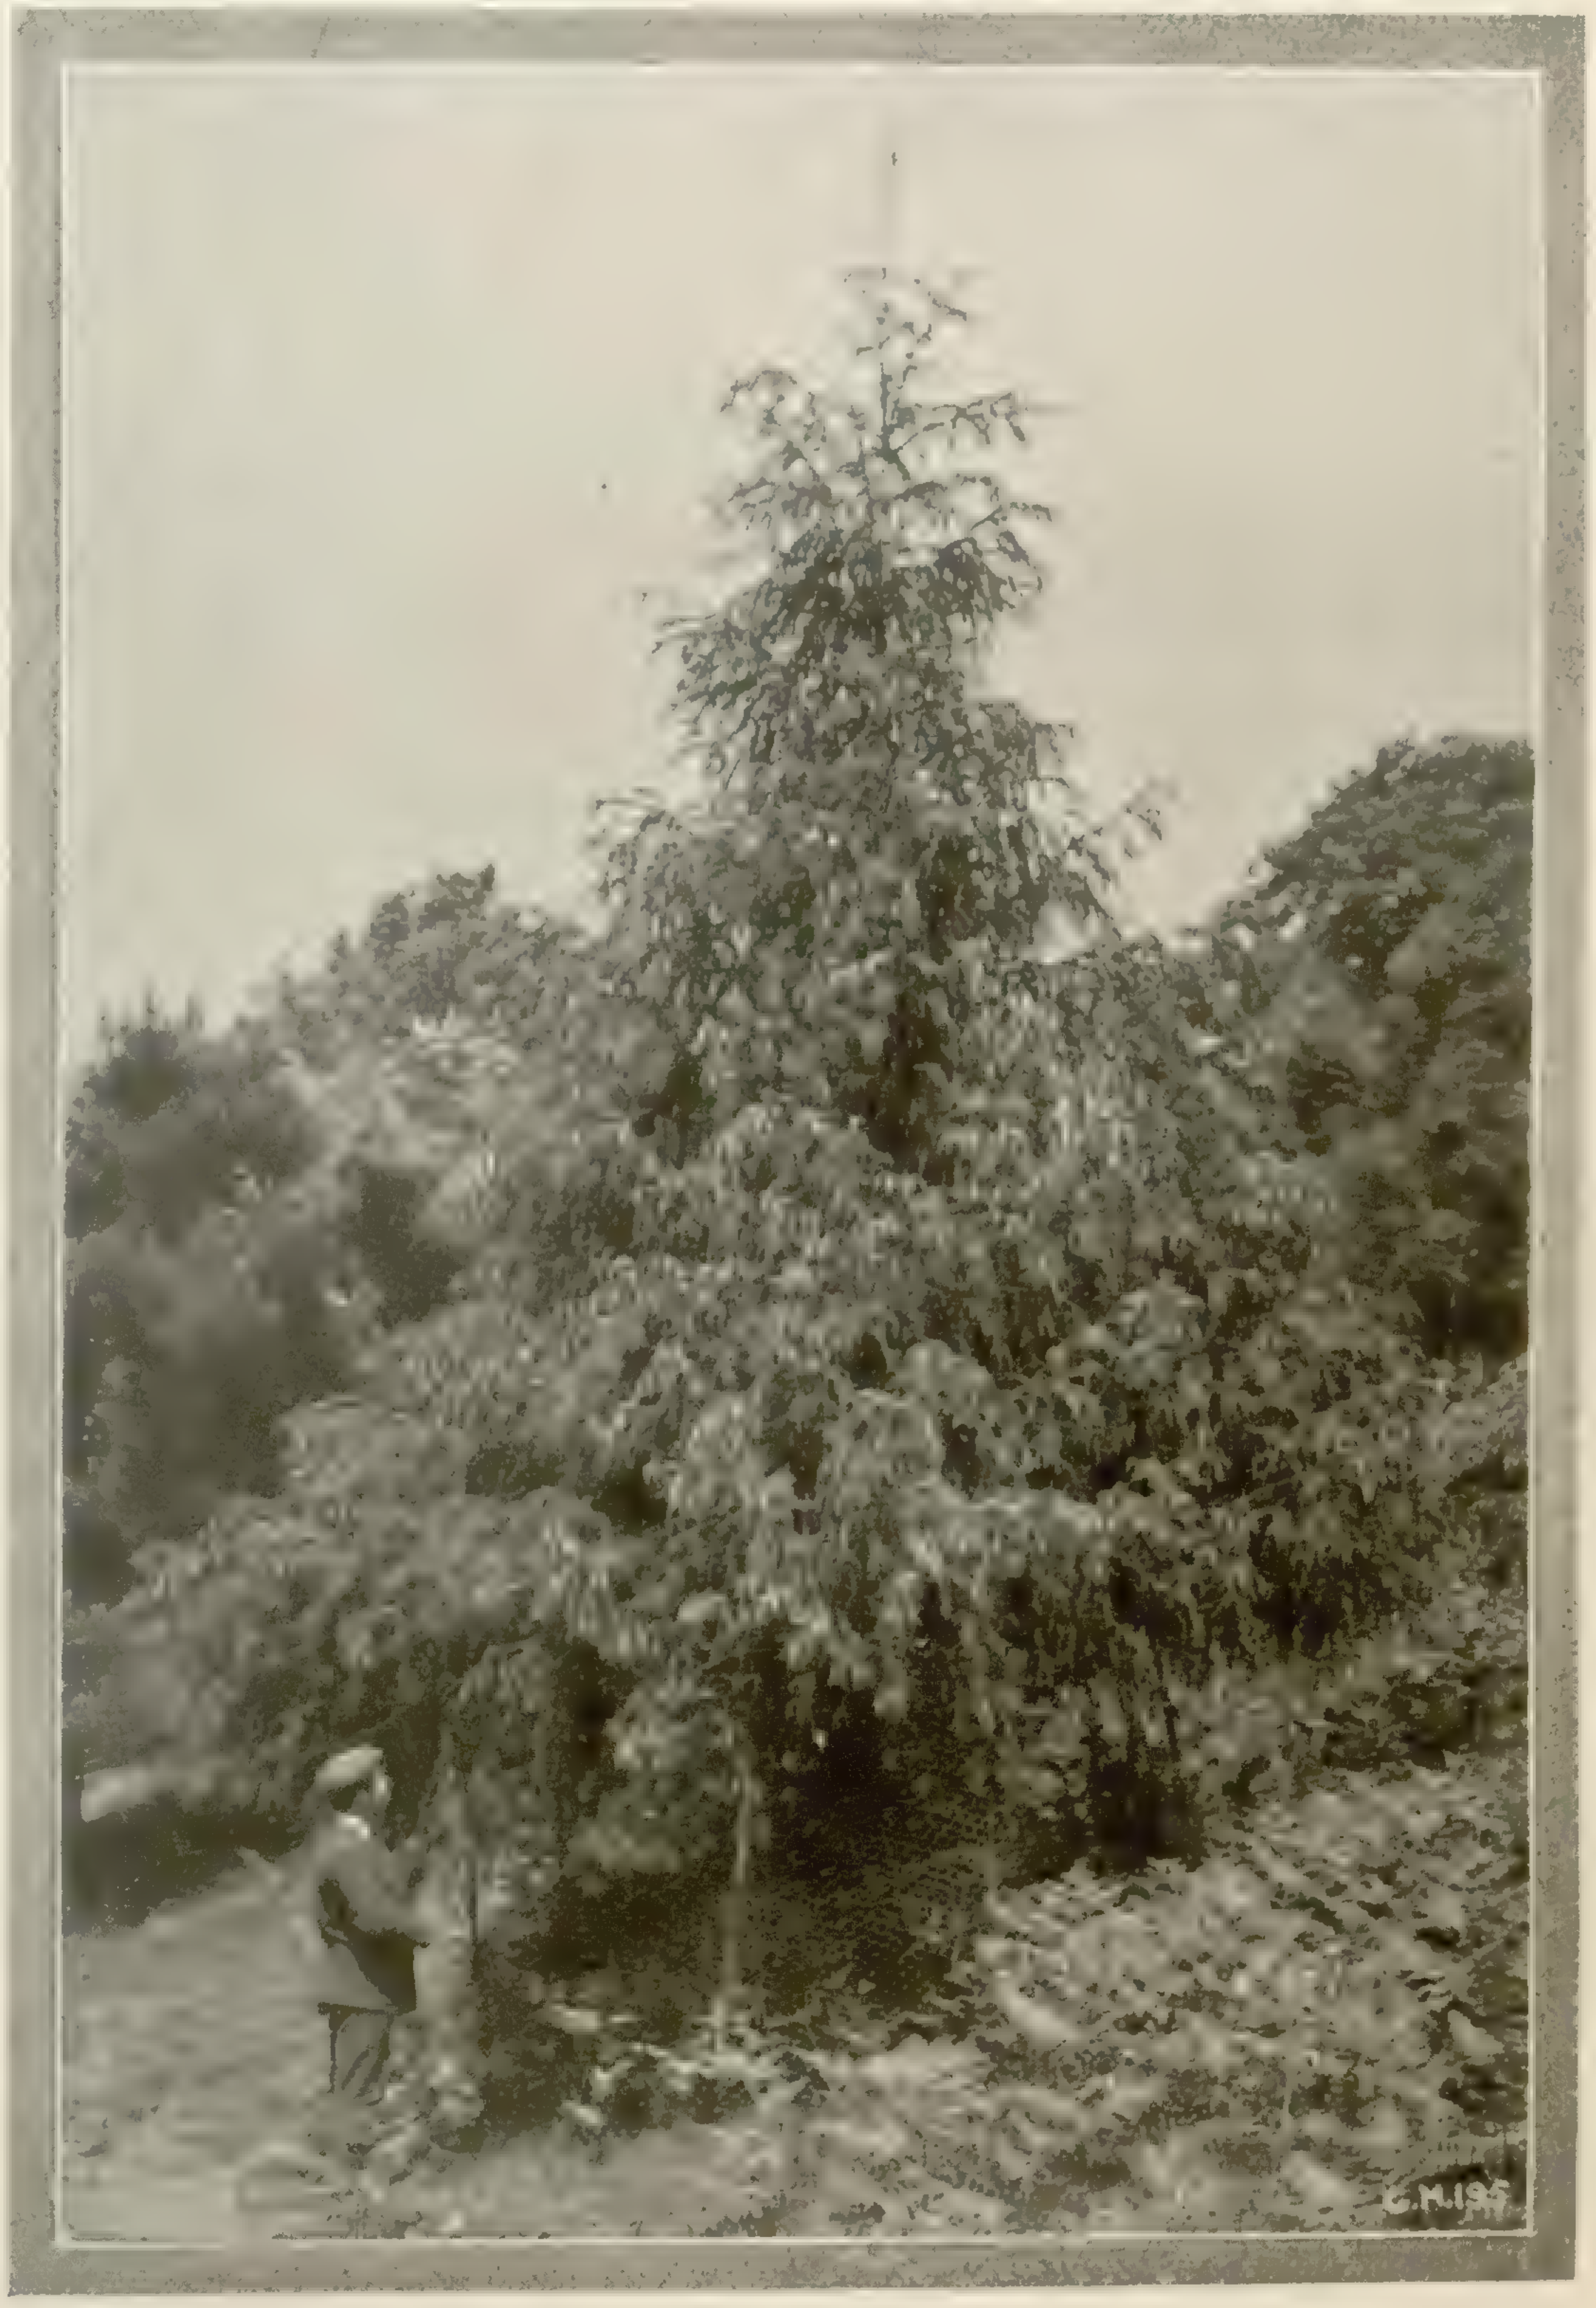
WILLIAM F. ROWLES.

PICEA MORINDOIDES.

The reference made in the GARDENERS' MAGAZINE of the 11th inst. to the figure of Picea morindoides, published in the "Botanical Magazine" (t. 8169) has brought several inquiries from readers specially interested in conifers. Several of our correspondents express themselves as desirous of obtaining information on the all-important question of the general character of the tree when of considerable age. We have, therefore, thought it advisable to give what further information is available, and an illustration of the unique specimen in the grounds of Leonardslee, Horsham, the residence of Sir Edmund Loder, Bart.

This tree occupies a position on the sunny slopes to the south-east of the wild garden for which Leonardslee has long been justly famous. The height is between thirty and forty feet, and as will be readily seen, the tree is well furnished from within a short distance of the base to the apex, is graceful in growth and elegant in contour. Originally there were two specimens at Leonardslee, but one occupied a position where it was desired to carry out some important alterations, and it had to be removed. Since the other tree was cut down the one remaining has had special attention, for like Sir Edmund Loder, Mr. A. W. Cook, the head gardener, takes a keen interest in the many noteworthy trees in the grounds, and consequently it is in a flourishing condition. There appears to be no record at Leonardslee of the origin of either of the trees, but this is not surprising considering that they must have been planted some years before Sir Edmund Loder purchased the estate.

According to Dr. Otto Stapf, who supplied the description accompanying the figure in the "Botanical Magazine," Dr. A. Henry has identified Picea morindoides with the spruce collected by Sir Joseph Hooker in the Lachen Valley, in Sikkim, in the course of his visit to the Himalayas in 1847. In his "Himalayan Journals" Sir Joseph Hooker writes: "Towards Lamteng the path left the river and passed through a wood of Abies Smithiana," and in a footnote he observes: "Also called A. Khutrow and Morinda, I had not before seen this tree in the Himalayas; it is a spruce fir, much resembling the Norway spruce in general appearance, but with longer pendulous branches. The wood is white and considered indifferent, though readily cleft into planks; it is called 'Seh.'" Further on the author states that the wood of this species "is employed for posts and beams" in the Lamteng district. Dr. A. Henry also identified the tree with a spruce collected in Chumbi by Sir J. Ware Edgar, who was then (in 1877) accompanied by Sir George King's collector Dungboo, and with the specimens collected by Mr. H. E. Hobson, when stationed at Yatung, and by Mr. E. H. C. Walsh, during the Tibet exhibition. To these the specimens collected by Mr. R. Pantling in Sikkim, and a second specimen collected by Dungboo at Chumbi, might in Dr. Stapf's opinion be added. It is also he considers evident that Gammie's Picea Morinda from the Lachung Valley is the same tree. "In my opinion," observes Dr. Stapf, "there can be little doubt that Dr. Henry is right in his identification of those specimens with Rehder's P. morindoides, although this implies the admission of a considerable range of variation in the shape of the leaf points, the density of the foliage, the shape of the cone scales, and to some degree also in the more minute details of the leaf anatomy. I have not accounted for this variability in the description, which is drawn up from the cultivated tree, but do not consider it greater than that observable in the common spruce."



UNIQUE SPECIMEN OF PICEA MORINDOIDES.
In the grounds of Leonardslee, Horsham.

Dr. Henry has gone still further, and included Griffith's Abies spinulosa in Picea morindoides, but there are no specimens of Griffith's tree either at Kew or the British Museum, or indeed anywhere so far as is known. The only evidence of identity is Griffith's description, and we regard it as unsafe to found the identification of a fir on such evidence.

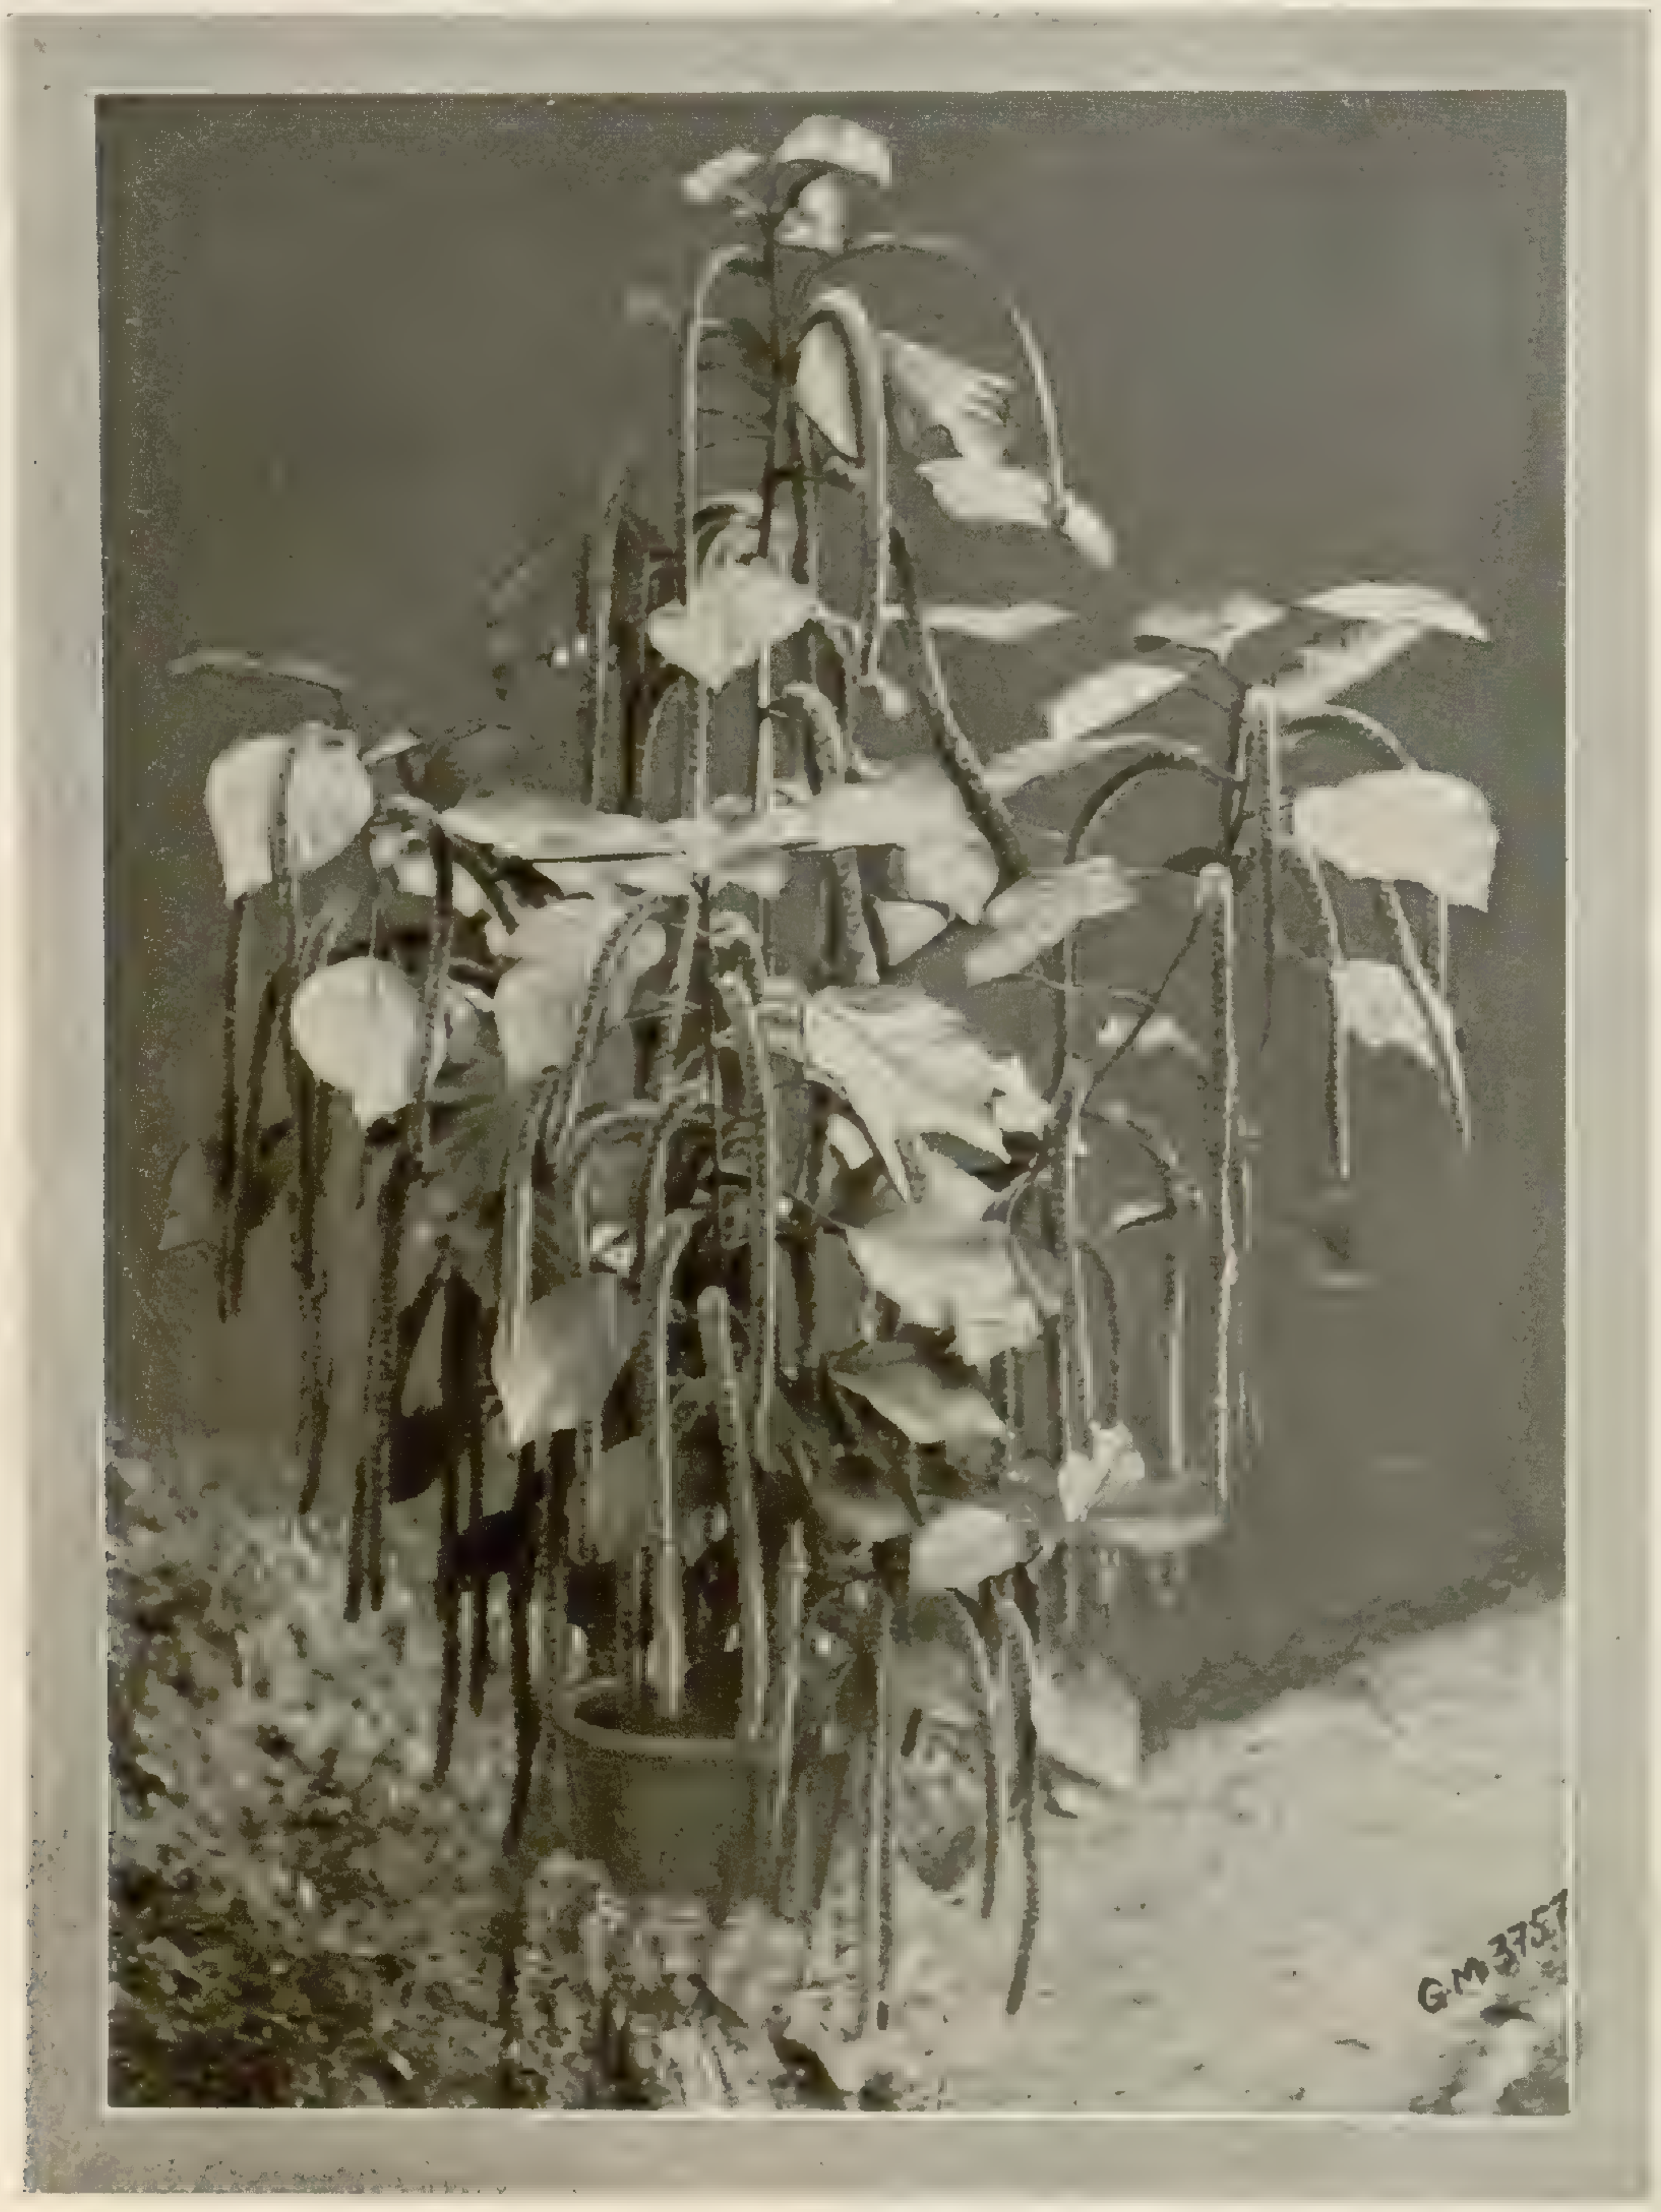
From these short notes it will be gathered that Picea morindoides is of interest to the systematic botanist as well as to the planter, and from the illustration given there will be no difficulty in seeing that it is a desirable addition to the coniferous trees grown for ornament.

G. G.

Digging Jerusalem Artichokes.—Jerusalem artichokes keep so much better in the ground that it is a mistake to dig up more at a time than will be consumed in, say, a week. The tubers should be kept as lifted, not cleaned of soil, and stood on the stone or cement floor of the vegetable shed. The point is to prevent their shrivelling. Garden critics, who know little of the inner workings of a garden, often wonder why artichokes are relegated to an odd corner. The chief reason is to allow of digging the tubers as wanted.—E. J. K.

MAIN CROP OF BRUSSELS SPROUTS.

Brussels sprouts are usually classed by gardeners as amongst the most important of the vegetable crops, and properly so, not only because they are usually very highly valued in the dining-room, but also because good crops afford a comparatively lengthened supply, and assist materially to satisfy demands made during a season when variety is difficult to maintain. Though highly valued as Brussels sprouts are, the crops are by no means at all times satisfactory, and various are the causes attributed to this. In some cases the variety is blamed for not being true to name, while in others the season, soil, or situation, is considered at fault. No one is likely to deny that instances occur when each of these assertions are justifiable, though more often probably the method of cultivation is to blame. It may be here remarked that our crops this season of the varieties Cambridgeshire Champion, and The Gem, are the most unsatisfactory I recollect having, and as their culture was conducted upon the lines which we have hitherto followed with invariable success, I feel that I should be correct in attributing our partial failure to the unfavourableness of the season.



A FINELY GROWN SPECIMEN OF ACALYPHA (SANDERI) HISPIDA.
From a photograph sent by a reader. The inflorescence rich crimson.

Raising Plants.

More depends upon the manner and the time of the year in which plants are raised and otherwise prepared for planting out than is at all times recognised. In the first place the seed is frequently sown too late, and then, perhaps, the plants are left crowded together in their seed bed until finally planted, and thus seriously injured. We find the last week in February the most suitable time for seed sowing, and then sow thinly in fine soil, placed over a warm bed of tree leaves in a cool pit or frame. The seedlings are kept as sturdy as possible by the structure being freely ventilated upon all favourable occasions, and no time is lost after they are large enough and sufficiently hardened in pricking them out. In carrying out this operation they are put about fine inches apart, in a bed of fine soil, placed upon a cool bottom in a cool frame. Here, except in severe spells of weather, they are left fully exposed until placed in their permanent quarters. After the largest plants have been pricked off, and the smaller ones have gained enough strength, the latter are pricked out upon an open sheltered border to furnish a successional crop, which often proves to be more useful than does the earlier one.

Preparation of Soil.

The cause of failure in some instances is without doubt planting in over rich or loose soils. This is especially inimical to success if the situation is low, and the weather during winter proves severe. Trenching and liberal manuring, therefore, which is so advantageous to many vegetables, must on no account be followed for Brussels sprouts. The plants keep sturdy, and freely form close, firm "buttons," when planted upon sound, firm land, and, moreover, when treated in this way they withstand severe weather comparatively well. A safe practice to follow is to plant upon stale dug, heavy loam, made quite firm, and in an open situation. If poor, of course, it should be dressed with manure before being dug, but ordinary well cultivated garden soil does not usually need to be specially manured for this crop. A plot that has previously carried a late crop of potatoes, for which it was manured, usually answers well. This for the Brussels sprouts should be merely dug, and when dry be firmed by treading.

Planting, etc.

An error may be thoughtlessly made by too close planting, and upon strong land especially, they have none too much room when placed in rows at three feet apart, and two feet asunder in the rows. With the trowel lift the plants carefully with good balls of soil, and plant them with the same help, making the soil quite firm about them. Planting is best done in dull, damp weather; watering should be attended to when necessary, and the plants be earthed up in order to keep them firmly in position, as soon as they are sufficiently strong for the operation. It is a common practice to cut and use the tops of Brussels sprouts at sometime during winter, but by doing this a late supply of small firm sprouts, that, if allowed to develop, in variably prove to be valuable, is sacrificed. T. COOMBER.

The Hendre Gardens.

ACALYPHA (SANDERI) HISPIDA.

This ornamental stove plant is very attractive at all seasons of the year, and is especially useful for furnishing the stages with a bright glow of colour during the dull months of winter Moreover, it is valuable for warm plant houses, conservatories, house, and table decoration. When grown in small pots, and confined to a single stem, it may be used in vases in the drawing-room, and is highly ornamental. The accompanying illustration depicts a very finely-grown specimen, and at once conveys to the mind the adaptability of this acalypha for decorative purposes.

Good plants are easily grown with ordinary stove treatment. Cuttings should be taken about February, and inserted in small pots and plunged in a warm bed in the propagating pit. Spray the cuttings daily, keeping them close until rooted. Air should be admitted gradually, and on no account should they receive a check, otherwise the lower leaves will be lost. When the plants become established they will form masses of roots on the surface, and will then require a stimulant three or four times weekly, in order to develop the rich crimson tassels to perfection. When in full growth they delight in a moist atmosphere, but when the racemes appear, overhead syringing should be discontinued, otherwise the inflorescence will be seriously injured. A suitable compost is one consisting of loam two-thirds and peat one-third, with the addition of sand and charcoal siftings.

Acalypha (Sanderi) hispida created a sensation when exhibited by Mr. Sander at the Ghent Quinquennial in the spring of 1898, and it rapidly acquired a high degree of popularity. It was introduced under the name of Acalypha Sanderi, but it was subsequently found that it had previously been described under the name of A. hispida. To Mr. Sander belongs the honour of introducing it to cultivation.

MID-SEASON PEARS.

The value of good pears at Christmas and immediately afterwards can scarcely be overrated, and while there is a large number of pears that may be classed as fair in quality, varieties that are really first rate are limited in number. I will admit that while one pear may be good in some gardens, in other gardens it may be almost worthless. This is probably due more to the nature of the soil than to other causes, although some regard must be paid to the stock on which the variety is grown.

Nearly all our trees are on the quince, only excepting those planted twelve years or more since. The quince is the most suitable for our heavy loam. The pear stock would give us too much wood, with the additional labour of annual root pruning or lifting. In fact on the quince stock our trees are benefited by lifting and replanting about every fourth year.

Pears being much in demand, and the essential point most required being flavour, it follows that we must have a large variety to test which really are best, and we also grow them on walls that give us three aspects for the purpose of lengthening the season, and also to find out on which aspect the quality is the highest, colour ranking next in appearance to flavour. In the production of colour we find a north-east wall, inclining to east, gives the most intense colouring to some varieties.

Beurré de Jonghe.—This is a very good pear, of excellent flavour, melting and juicy. On reference to my notes, it is above medium size, this may largely depend on the crop and age of tree, it is, however, of a good size for dessert, and makes an excellent Christmas pear.

Beurré d'Anjou.—This pear was finely shown during the past autumn by the British Columbian Government, and while they were good outwardly they did not rank in flavour with Devon-grown fruits. My note on this variety places it next to Doyenne du Comice in quality, which is giving it a high position, and as it follows that fine pear in season it is a variety worth growing; above medium size, melting, and juicy. Whether the flavour of our fruits was exceptional I cannot say, but as showing the variability in quality, Mr. Bunyard places this variety in the list B in his fruit catalogue. Evidently it is not of such good quality with him as we have had it, but some sorts, which are of good quality grown in the Allington Nursery, are only second rate with me.

Beurré Renee.—Another pear which Mr. Bunyard lists with the preceding one is Beurré Renee, which is excellent with me. In fact I was agreeably surprised to find it of such excellent quality when it was tested. This was ready at he end of December. The fruits were above medium size, rather long, bronzy red on the side exposed to the sun.

Beurré d'Aremberg.—Comes of good size, very juicy, flavour good, and a useful one to form a succession in December.

Beurré Dubuisson.—Above medium size, very melting, juicy, and sweet. I find an extra note against this variety for quality. Apparently a good bearer, and a most desirable kind to grow. Mr. Bunyard, in his fruit list, speaks very highly of this pear, which, from my own knowledge of it, I can endorse.

Madame Andre Leroy.—A useful pear in December, sweet, of very fair quality, but not equal to the preceding varieties. quite distinct in shape from other kinds.

The varieties enumerated I have selected as having been extra good in a season wherein we have not had an excess of sunshine. Many kinds of pears have been sadly deficient in flavour, and apples have been more so. The season when the varieties of pears noted would be ready, will vary according to the locality in which they are grown, but in their order of ripening with me they should, in colder parts of the country, extend through December and January, and so connect with the later varieties, to which I will refer in a subsequent issue. T. H. SLADE.

Poltimore Park Gardens.

DECIDUOUS CALANTHES AT BUXTED PARK.

The illustration we have the pleasure of giving herewith of a group of the magnificent specimens of Calanthe Veitchi in the gardens of Buxted Park requires but the briefest reference, for a glance is sufficient to enable one to see that the development of the plants is of a quite exceptional character. It should, however, be said that the eleven specimens represented in the group form but a small part of the stock under the charge of Mr. H. C. Prinsep, who is a past master of the cultivation of deciduous calanthes as of many other important subjects. There must be at least four or five dozen, and they were so closely matched in size and flower production that there was but little difference between them when the flowers were at their best.

The bulbs were put in the pans in which they are flowering on March 5, 1907, the pans were provided with efficient drainage, and the compost used was formed with turfy loam and dried cow dung. Evidently the time of potting them up was suitable, the compost adapted to their requirements, and the other cultural conditions favourable to a vigorous growth, for by the end of the season the largest bulbs attained a length of eighteen inches. When in full growth the leaves were mostly four feet in length and of proportionate breadth. From such vigorous plants as these much might well have been expected, but we venture to say that but few would previous to the time when evidence of flower production was forthcoming have expected so dense a forest of flower spikes as that produced. The majority of the bulbs produced four or five flower spikes each, while the strongest had six each. The largest of the spikes were six feet six inches in length, near the base they were as thick as a man's thumb, and at two feet therefrom they branched, as the best means it may be presumed of getting rid of their superfluous vigour. We have stated the facts relating to these remarkable specimens in the plainest manner, that those of our many readers who are interested in deciduous calanthes may have no difficulty in accepting them.

Mr. Prinsep has kindly promised to give within the next few weeks the details of the practice by which he has achieved such splendid results, and with his notes we shall present an illustration of a single specimen that will show even more clearly than does the group herewith so admirably illustrated, the high degree of development to which the calanthes at Buxted Park have attained.

Lettuce.—If salads are required daily a pinch of seed of an early variety, such as Tom Thumb, should now be sown in a pan or box and be placed in gentle heat. Transplant the seedlings, and put them rather close together on a hotbed, when large enough to handle.—T. W. BIRKENSHAW.

SEED ORDERS.

Most of the leading firms have now distributed their catalogues for 1908, and it should be our first consideration at this season to make a selection of the vegetables we intend to grow and determine the quantities of each. In these progressive days many new varieties and selections of vegetables are offered, and it must be admitted that in most cases much improvement has been brought about. The safest plan in making out seed lists is to rely upon the varieties that we know are of a high order of merit, and to experiment with novelties on a comparatively small scale and with care till we satisfy ourselves of their value. Should they be found in anyway to surpass the older kinds they may then be substituted for them.

Probably there is too great a tendency to grow too many varieties of each vegetable, and I would, therefore, say that often better results would be obtained if we grew a less number and limited them to those which specially suit the soil and situation of the particular garden. The pea family especially is one that varies greatly under different conditions. A friend of mine whose garden stands at a high altitude assures me that he entirely depends upon a selection of the Duke of Albany to give a continuous supply of peas through the summer and late autumn, making a sowing each alternate week. Here, it is given to mildew, and we only grow a limited quantity of it. Admitting its good qualities on the table, there are other varieties that give us better returns, and are less subject to fungoid attack. I only give the above as an example to show how peas vary, without in any way suggesting its general adoption as in the case of my friend. Our seedhouses are sending out varieties that are suited for early and late seasons, and speaking in a general way they should be selected accordingly in making out the seed list, though to a somewhat limited extent.

An important point in the work of supplying a private establishment with vegetables is the carrying of each crop over as lengthened a period as possible, without having too great a quantity at one time. This is only managed by early and late sowings. Seedsmen of late years have assisted us materially with some vegetables in prolonging the season. In cauliflowers we have now varieties that will yield to light forcing much better than the older kinds, though some of the latter are unsurpassed for general and late use. Potatoes also vary in different soils and situations, both with regard to their eating and cropping properties. There is a great choice in early and late varieties to meet requirements, and I strongly advise a liberal amount of new seed being planted each year. Potatoes grown on the same land will soon show signs of deterioration. and a light crop be the result.

The foregoing, as far as the changing of potato sets is concerned, applies to a great extent, if not equally, to its near relative the tomato. This plant has been wonderfully improved of late years, being more prolific and the fruit of more useful size and shape, with solidity of flesh. Some of the new forcing French beans that are offered are worth careful consideration when ordering seed, as they are very free bearing and of excellent quality.

The climbing French bean is not grown to the extent it deserves to be, especially under glass late in autumn and early in winter, and thus carry on the supply after the outside crop is over. If this has not been included in the past a trial should be made. The new additions to the scarlet runner beans as far as length of pod is concerned are an improvement, though with good cultivation some of the older standard varieties are difficult to surpass from a productive standpoint.

Carrots of the French types are very valuable for forcing purposes to give the earliest supplies; and the intermediate type as the result of constant selection is now of much value to the gardener, being more economical in use, and should constitute the main crop. The turnip-rooted beet is useful for an early sowing on a warm border and should be grown in quantities in proportionate to the requirements of the kitchen. For the main sowing the longer roots are preferable, being exceedingly beautiful in colour and outline, as well as being better adapted for late use. Broccoli that are sufficiently hardy to stand our severe winters are difficult to select. for a regular supply; the hardier appear to be those that turn in about April.

I cannot close my remarks without referring to the onion, which is so important to those who only grow for culinary purposes of the establishment, and not for exhibition; I advise them to select some of the medium-sized varieties, and not to rely upon the sensational large sorts. The above are a few suggestions to the beginner in making out their first seed list.

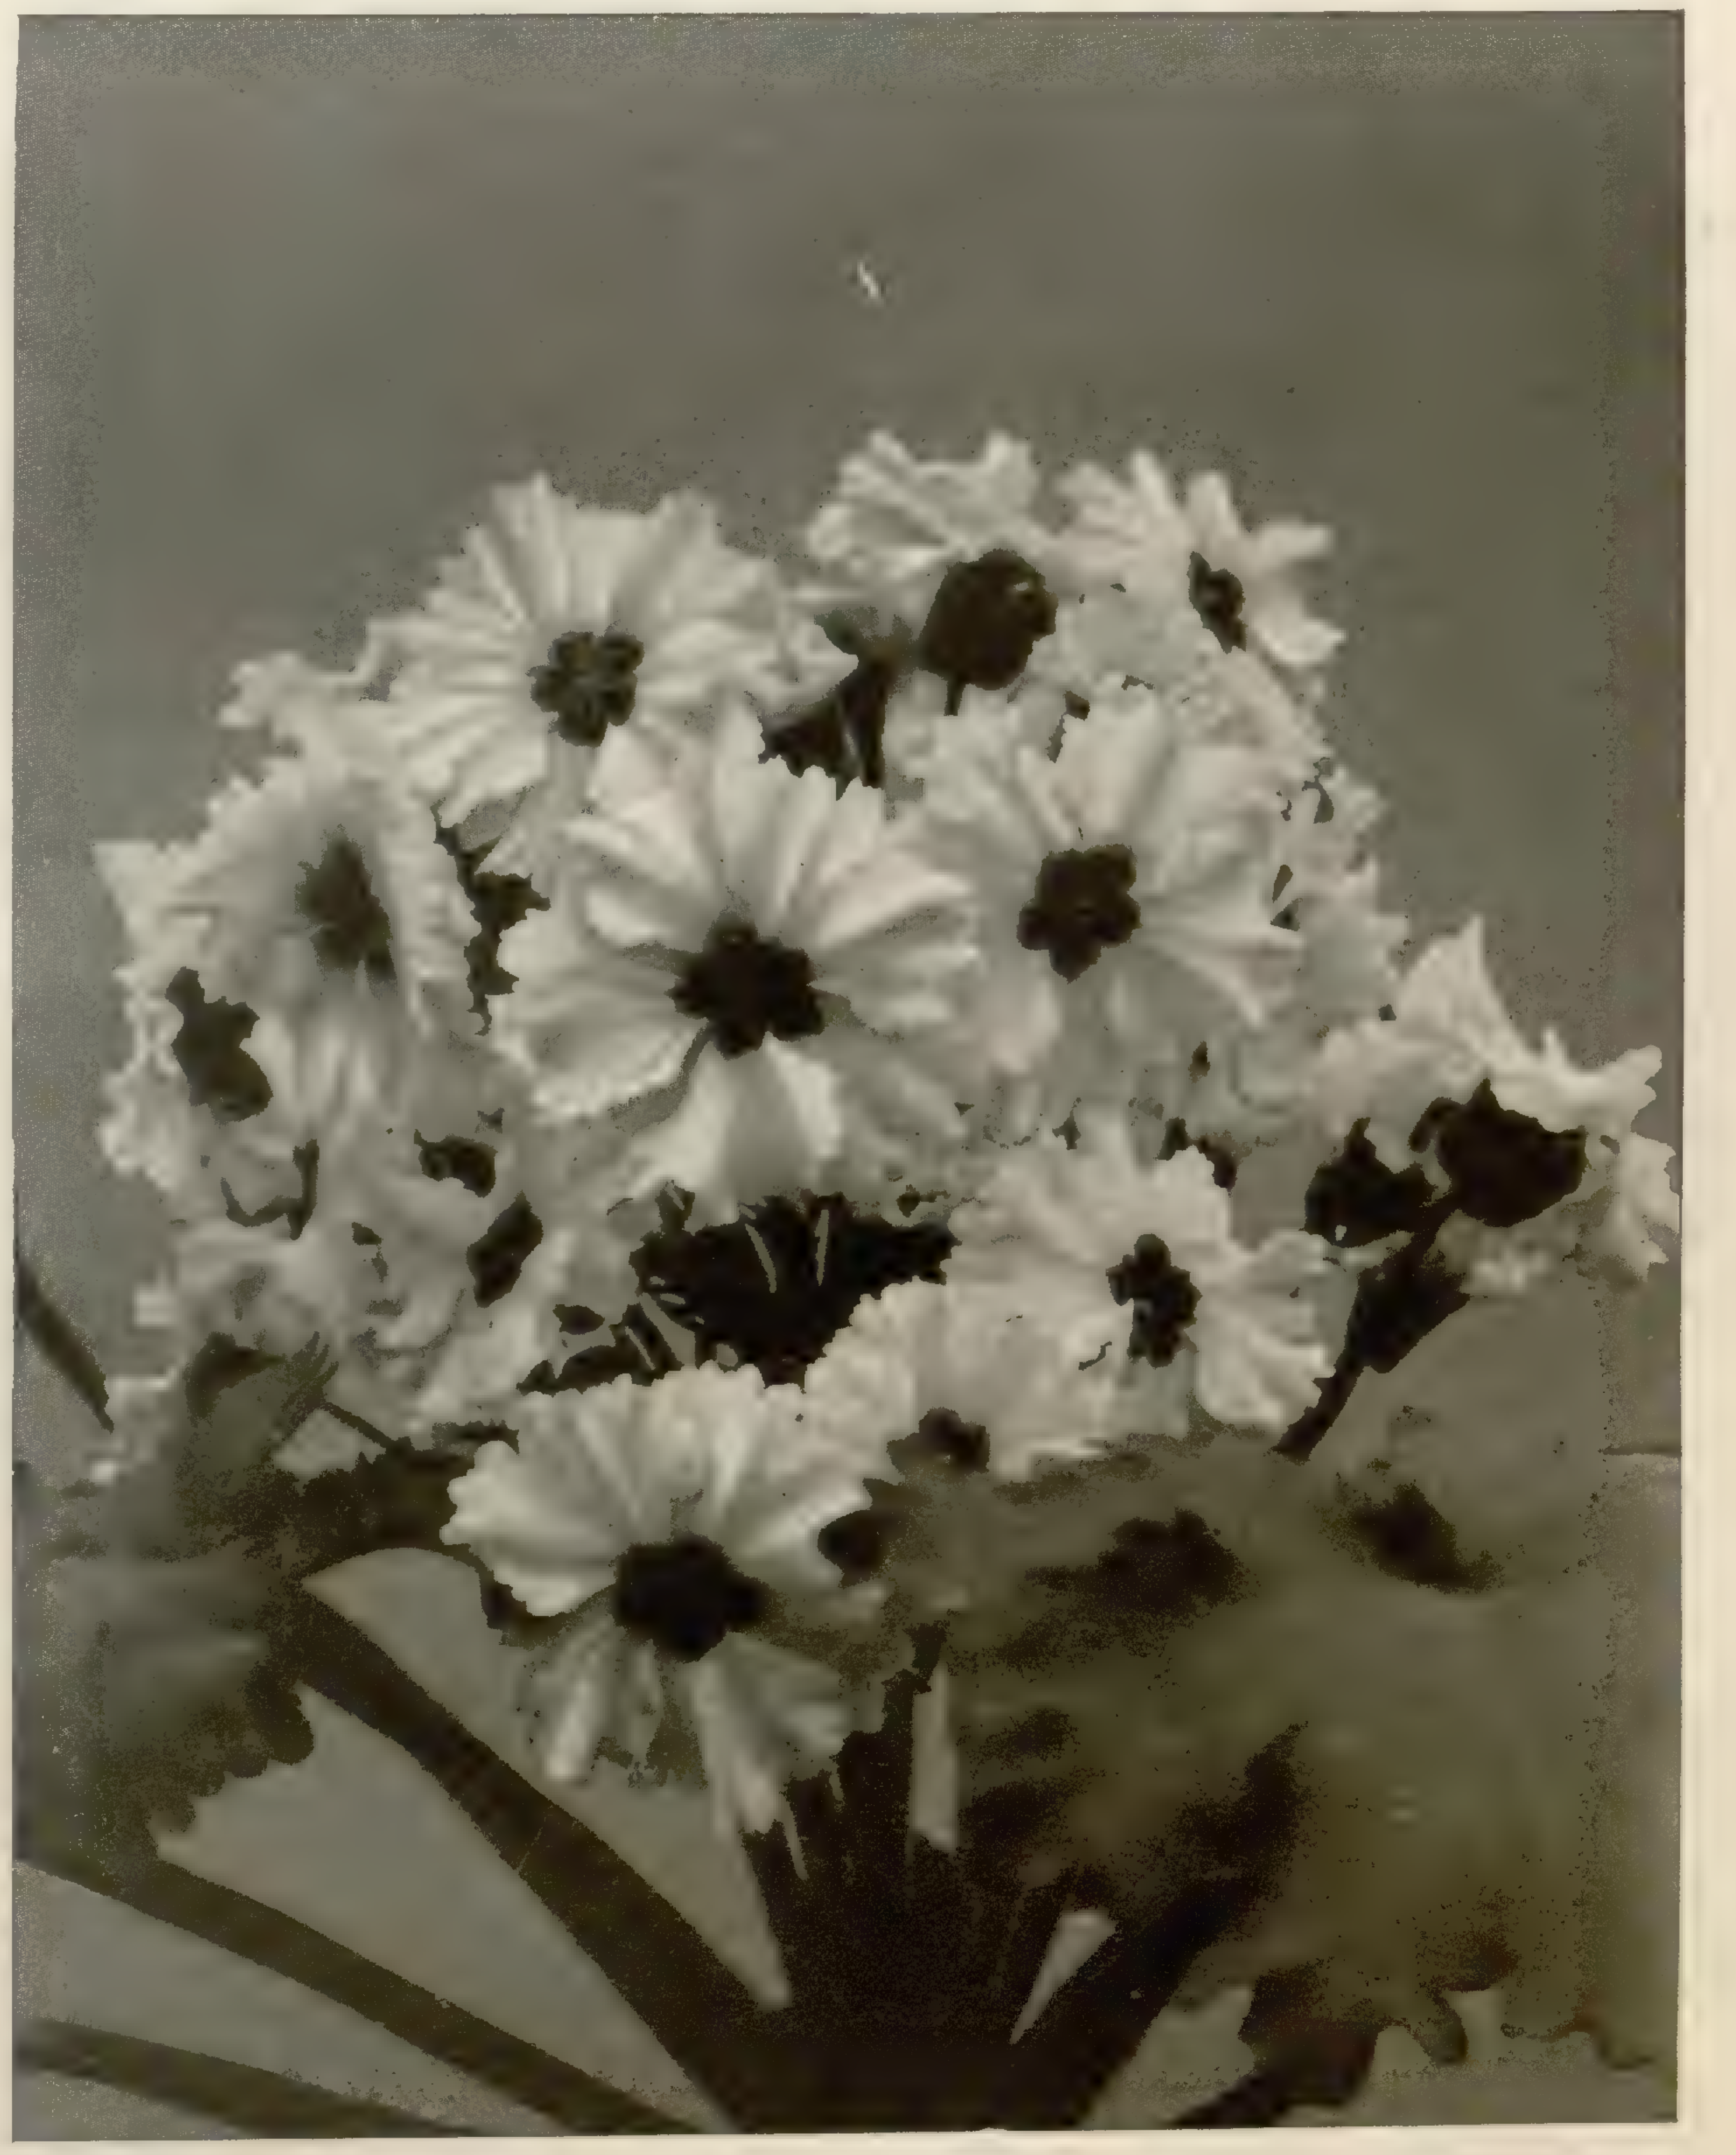
I have not given names of varieties in dealing with some of the more important crops, but in the course of the season I hope to mention varieties that I have found the most desirable for various purposes.

Charles Flack.

Cholmondeley Castle Garden.

NEW PRIMULA, QUEEN OF THE NORTH.

The beautiful new primula, Queen of the North, which Messrs. Dickson, Brown, and Tait, of Corporation Street, Manchester, have introduced this season, is so highly meritorious that it can hardly fail to attain to a high degree of popularity. The superb form and fine texture of the flowers are so well shown in the accompanying illustration as to render description unnecessary; but it is desirable to say that important as are these attributes, the claims of the variety for consideration do not wholly rest upon them. Rather do they rest upon the distinct combination of colouring the variety affords, and the effectiveness of the plants when in bloom. Queen of the North was raised by Mr. A. Traill, of Fulshaw Gardens, Wilmslow, and is described as having been raised from a cross effected between Avalanche, one of the finest of the pure white varieties belonging to the florists' type, and The Lady, a stellate form bearing white flowers, and remarkable for the deep red colouring of the leaf stems and flower stalks, and the deep bronzy hue of the foliage. In this form the characteristics of the two parents are happily combined, the flowers being like those of Avalanche in size, form, and purity, while the flowers are borne on long stalks, and the leaves and stems are very dark in colour as in The Lady. The large white flowers present an extremely pleasing contrast to the dark hue of the foliage, and suitably arranged well-flowered plants produce an effect that at once arrests attention.



NEW PRIMULA, QUEEN OF THE NORTH.

A fine form, introduced by Messrs. Dickson, Brown, and Tait. Flowers pure white, and the leaves and stems dark bronze green.

SOME RARE SHRUBS.

◆

Clianthus puniceus.

This comes from New Zealand, and is a common plant in the south-west, where it is almost invariably grown against a wall, though I have seen a specimen in the open in bush form. Here a few flowers may usually be cut on Christmas Day, but it is not until May that the plants are at their best, when they are sheets of crimson. The blossoms of the white-flowered variety are greenish-white in tint, and are much inferior to the type in beauty. The two, however, when planted on the same wall, as they are here, make a pleasing contrast.

Eucryphia pinnatifolia.

This native of Chili is a charming sight in August when covered with its large white flowers, which, in form, closely resemble the blooms of Hypericum calycinum. It is quite hardy in Devon and Cornwall. The finest specimen in England is probably that in Mr. T. B. Bolitho's garden at Trewidden, Penzance, which is eighteen feet in height and twelve feet in diameter.

Fremontia californica.

This shrub has an unfortunate habit of dying out when it has attained a large size, without apparent reason. It is very ornamental when bearing its bright yellow cupped flowers, about two inches across, which it carries for many weeks. At Newton Abbott there is an example over eight feet in height, which is in good health up to the present.

Guevina avellana, or the Chilian Nut.

The best specimen of this in England is that in the gardens at Greenway, near Dartmouth. It is twenty-two feet in height and about twenty feet across at the base. The great, much-divided, glossy leaves are very handsome. The flower spikes, some four inches in length, carry numerous tiny white blossoms with narrow recurving petals, and are borne in August. These are followed by large marble-like fruits, at first green, then red, and eventually purple. It is a very rare plant.

Lagunaria Patersoni.

This shrub is a native of Norfolk Island. It is probably not in more than two or three gardens in England at the present time. The entire leaves are three inches in length and one inch in breadth, and the white flowers, which somewhat resemble a camellia, and have very stiff petals, are over two inches across. A plant here was killed last winter by ten degrees of frost, but another, which was protected, was saved.

Leonotis leonurus.

This shrub, from the Cape of Good Hope, was a glorious sight in September, 1906, when every shoot held many large whorls of orange scarlet flowers, some of these being over a foot in circumference. It was a brilliant object for more than a month. The plant is alive, but was much damaged by the winter.

Leptospermum scoparium.

This New Zealand shrub, or tree, is common in the south-west, where it has attained a height of twenty-five feet. It is a pretty sight in summer when freely studded with its small single white flowers.

Osteomeles anthyllidifolia.

This native of the Pacific Islands appears fairly hardy, as it has been uninjured by last winter's frost, which was unusually severe for this district. Its foliage is attractive, and its clusters of white hawthorn-like flowers are delightful in the early summer.

Ozothamnus rosmarinifolius.

No plant can rival this Australian shrub in abundance of flower, for in July it is so smothered with bloom that not a leaf is visible. The flower sprays, if cut when the tiny blossoms are fully expanded, and hung in a dry room, will retain their freshness for a year or more. The finest specimen in the south-west is probably that at Trewidden, which is nine feet in height and as much through, and is a cloud of white when in flower.

Polygala Dalmaisiana.

This small South African shrub bears its magenta-pink flowers in April, these being an inch across. It rarely exceeds three feet in height, and has passed unharmed through the winter. It is a pretty thing when blooming freely.

Rhaphithamnus cyanocarpus.

A native of Chili. It has shining, heart-shaped, dark green leaves, about half an inch long. The flowers are tubular, mauve-blue in colour, and are carried in clusters of six. The blossoms are followed by violet-blue berries. There is a fine specimen, twenty feet in height, at Menabilly.

Sutherlandia frutescens.

A South African plant bearing racemes of crimson-scarlet flowers, somewhat resembling blooms of the clianthus. In summer, when smothered in the brilliant flowers, it is a striking sight. The flowers are followed by large inflated seed pods.

Viburnum rugosum.

This is a rare shrub from the Canary Islands, and I only know of it in two gardens. It bears large flat flower heads about eight inches across, and has attained a height of twelve feet in an open position. It appears perfectly hardy in the south-west.

Westringia triphylla.

An Australian shrub, with small rosemary-like leaves, bearing starry white flowers about three-quarters of an inch in diameter. It has passed through the winter uninjured. There is a good specimen at Tregothnan. S. W. Fitzherbert.

Kingswear, South Devon.

THE GALTONIA.

We have none too many hardy bulbous plants in autumn, especially among those of effective character which are able to hold their own among the flowers of the border in that season. In few places are the best hybrid gladioli sufficiently hardy to come under the category of hardy bulbs; while the montbretia is also tender in certain districts, and to do it justice requires annual replanting at least, and, in the case of the newer varieties wintering in a frame. It is even doubtful if the subject of this article is enduring enough to be properly classed as hardy, although it is so in the greater number of gardens in the larger part of the United Kingdom.

It is, however, justly entitled to be classed among hardy bulbs in so many gardens that it may well be spoken of as such, and may well be classed among the flowers worthy to be considered permanent occupants of our borders and beds. In respect of its beauty there can be no question as to its worthiness. Its noble mien; its unique appearance; and its purity entitle it to a high place among our garden flowers.

The galtonia, which belongs to the natural order Liliaceæ, is one of the numerous bulbous plants which we owe to South Africa, and its name reminds us of the distinguished Francis Galton, whose "Narrative of an Explorer in South Africa" has become a standard work of its kind, although the march of events in that portion of the African continent has rendered obsolete many of his remarks and descriptions. One is glad, however, to know that the name of such a distinguished man will be kept in remembrance by this stately and beautiful plant; that of Hyacinthus, so far as applied to it, being practically abandoned.

There are two species in cultivation, and it is in one sense unfortunate, but in another satisfactory, that the finer of the two, Galtonia candicans, should have been introduced to cultivation before its congener, G. princeps, as the latter, although bearing such an imposing specific name as "princeps," is distinctly inferior to the former in stature, purity of colour, and in the size of its racemes and single flowers. Of Galtonia candicans it may be said that we have few nobler bulbous plants, save the lilies, at its season, and that, whether we employ it in borders among other flowers, or in effective masses in the grass, or in beds by itself, it may be reckoned indispensable in its season.

Its appearance is familiar enough to the greater number of flower lovers nowadays, yet one comes across many amateurs who have not had an opportunity of seeing the galtonia in its best form, when it may be met with towering up to six feet high, and bearing its handsome racemes of from fifteen to twenty pure white, drooping flowers, and forming one of the finest plants of the autumnal garden. Its congener, G. princeps, is less beautiful, and as its flowers are of a greenish white, it is not so valuable as a contrast to blooms of another colour or so pleasing in itself. To the gardener many uses for the galtonia will suggest themselves, but the writer has, for example, seen it employed to great advantage in association with Gladiolus brenchleyensis and Salvia patens; while in wild gardening or for bold clumps in large borders it has been met with in many exceedingly beautiful combinations.

Among other recollections is that of a long pergola in front of which was a broad line of this noble flower, constituting a charming picture against the rough timbers of the pergola clad with plenty of greenery, which formed a background for the galtonia.

Although one speaks of this plant as six feet high, and one has occasionally met with it even taller than that, it is frequently seen in a much dwarfer state, four feet being quite a general height, a reduction of stature due to poor treatment.

Galtonias ought to have a free and rich soil, deeply dug, with some old-rotted manure at the bottom, beyond touch of the bulbs themselves; while in stiffer soils a liberal supply of leaf-mould or peat should be mixed with the remainder. Some sharp sand immediately about the bulbs is beneficial in heavy soils, and in gardens where drainage is imperfect care should be taken that the drainage of this portion of the garden is above suspicion. Planting is best performed in March, or even as early as February if the soil is in good order, and one would advocate a fair depth—six to nine or even twelve inches—for the bulbs. At a depth of nine inches in moderately heavy soils the galtonia generally proves hardy, but it is desirable to protect it during the first winter with some litter or ashes—a useful precaution with many bulbs, which require a simple covering for the first winter after planting only. Should the plants pierce through the soil early, although this seldom happens, a little straw or a few branches about the beds will be helpful and may prevent the young growths being cut by late frosts. This is more necessary with newly-imported bulbs planted in late autumn than with those put in the ground at the proper time in spring.

In cold districts where it does not prove hardy, the galtonia ought to be lifted when the leaves have become yellow, and stored in dry sand or elsewhere beyond the reach of frost until spring.

The after cultivation of the galtonia requires no detail, but it will be well for those who have exceedingly exposed gardens to stake the plants, although this is a great disfigurement to them and this noble plant is much more beautiful when left unfettered. S. Arnott.

Bedding Plants in Winter.—There are some owners of greenhouses who put away their bedding plants in winter, much as they put away their tennis rackets and cricket bats, and with as little thought for their welfare. This is a grave mistake. Geranium cuttings may damp off at the soil, or turn black and die back at the tips of the shoots; pans of lobelias may catch a drip in their midst from the roof, and decay with alarming rapidity outwards; verbenas may mildew and relapse into an unhealthy state in an incredibly short time. These are only a few of the things which may happen—there are lots of others, all of which goes to teach us that bedding plants should have a little attention in the dull months of winter, and not only when they are in strict training for filling beds and borders. Much time need not be given to them.—E. J. K.

Dimorphanthus Mandschuricus variegata.—What a magnificent subject we possess in the above for planting in the sub-tropical garden, as dot plants in large beds, or in prominent positions in the shrubbery! Of recent introduction, it has proved itself quite as hardy and vigorous as the type, while the silvery-white variegation is of the most beautiful description. We purchased a dozen young trees a couple of years ago at a considerable cost: they are grafted on the common stocks, which doubtless accounts for their extraordinary vigour. I understand the price has not yet fallen below five shillings per plant, but, seeing the stems are well clothed with buds, they should soon be plentiful enough, as these speedily develop if the top is removed, and, as is well known, the roots throw up a quantity of growths if laid horizontally.—Walter H. Aggett.

THE STATUS OF A GARDENER.

For many years I have often mused and thought how lucky we gardeners ought to think ourselves, from the fact that we have a journal named after us. Gardeners' Magazine—the very name cheers us up, for the butler has no corresponding herald nor the coachman his gazette. All the other happy family of horticultural papers, save one, prefer to take some other title connected with the garden, and do not so closely bind themselves with us. Whenever I am waiting at a railway station where there is a newspaper stall, I look at the papers arranged with their titles to attract the eye of the traveller, and it always cheers me to see amongst the vast array the well-known face, to us, of the Gardeners' Magazine. Reminiscences are not usually of much interest, except to the individual concerned, but when I consider at times the different conditions and the number of different places I have perused my "G.M.," it is interesting to me; often I have picked it up in a bothy, and it has cheered me when I have been fagged out with watering strawberries and French beans on shelves; I have rested for a time, and read its pages before I have had my tea, which meal we usually had to prepare by first lighting the fire before we could obtain the necessary hot water. These meditations might be prolonged indefinitely, and fill a whole page, but before I plunge into my subject I must mention, and apologise for, one trait in our character as gardeners—we, unfortunately, are apt to think the "G.M." is published for our especial benefit, ignoring the fact altogether that, while it looks closely after our interests, it is a popular paper amongst thousands of ladies and gentlemen, and amateur horticulturists of all descriptions, who have but little interest in gardeners and their ways.

My subject is the status of a gardener, and, of course, to illustrate it I must have an ideal in view. In very large establishments, in various parts of the country, there are two classes of servants, viz., upper servants and under servants, and the line of demarcation is very severely drawn when all the servants of the place are assembled together, we will say for Christmas festivities or the annual servants' ball, or any such like occasion. In the household establishment the house steward, housekeeper, cook, chef, if one is employed, if not a woman cook, butler, ladies' maid or maids, valet, head nurse, groom of the chambers, etc., are upper servants. The outside servants who rank equal are, head gardener, farm bailiff, stud groom, clerk of the works, forester, possibly the head gamekeeper, and one or two others. They have their dinner and supper in the house steward's room, with a boy or strong lad called the steward's room boy, who is found undress or morning livery to wait on them. The liveried servants are all denizens of the servants' hall, in which place they have their meals. These remarks, in a general way show the position of a head gardener amongst the servants, but there is also his position to consider amongst other people about the estate, farmers and tenants generally. Now this is shown on such occasions as the coming of age festivities in connection with the heir, or on occasions of local or national rejoicings. In a large place the head gardener is usually friendly with tenant farmers, and associates a good deal with them, and on the occasion of these gatherings they cannot understand why their friend the gardener is not amongst the throng. The reason is that in strict etiquette servants rank one stage lower in the social circle. Now I must conclude my remarks by saying that my ideal has been a head gardener at some very large country place, where his emoluments are £100 a year, with good house, fuel, milk, vegetables, and light provided for him, where he never soils his fingers with manual labour, and where he is always what is termed in Lancashire "at a loose end," that is, not tramelled by any rules of time, etc.

Young gardeners will now find these places very scarce, as conditions have altered, and many of these fine old places are not kept up now, or if they are it is at a greatly reduced expenditure. There are more gardeners required than ever there were, but they are mostly of a different class, to whom my notes will not apply. It is always well to set up a high ideal, but if it is not reached we have to be contented with a lower one.

For the benefit of the rising generation of gardeners who are still toiling in the forcing houses in these old walled-in gardens, and hoping for better days, I will recommend three courses of action to them, and advise them not to trouble themselves so much about the status of a gardener, but look more to the financial side of the profession, and also the likelihood of fixity of tenure. In the first rank is the orchid specialist, where orchids are well grown, and much money is expended. We are visited periodically by representatives of all the leading orchid growing establishments, and I know personally a good many growers, and from conversations I have with them I find out the financial side of affairs much better in contradistinction to the old French beans and strawberry plants in pots. In the second place I will place the position of superintendent of a public park in one of our large towns, where there are several parks, recreation grounds, etc., and you become snugly ensconced as the chief. Dynamite will not blow you out, no leaving through death of employer, reducing establishment, or some fancy whim, desirous of a change, which has seized the employer. In the third place I would suggest the trade, instead of private service; try to qualify as a departmental foreman or a manager to one of our good old and substantial firms of nurserymen. They scarcely ever change their employees.

Some readers will say, why not try a business for yourself? A very laudable thought, but it is not given to everyone to succeed in business. I always remember the words of an old gardener when I was young. He said, never be afraid of work, there always were, and always would be, "hewers of wood and drawers of water." But he had neither hewn nor drawn for forty years, as he had one of the grand old places where there were plenty of assistants to do the work. The status of the gardener deserves more than a passing thought, and I think I have shown that an upholder of Adam's profession ranks high, and takes high place in a large and well-conducted establishment. W. M.

Cheshire.

Zonal Pelargoniums. — Plants having finished flowering should be cut down to three or four eyes. Place them in a heated pit, and keep rather dry until they start into growth. Select the strongest and most vigorous growths as cuttings for increase of stock. Insert them singly in three-inch pots filled with a mixture of loam, leaf-soil, and sand. Water and place in a temperature of about 50 degrees, where they will soon form roots. The plants that were placed in their flowering pots in the autumn may now be brought into the house. A light airy house, with a warm and rather dry atmosphere, is the structure zonals flourish in. Those in three-inch pots may be shifted on into 4½-inch or six-inch pots, well drained, using a compost of fibrous loam, leaf-mould, and sand, adding bonemeal, and potting rather firmly. Zonals do best in small pots, and require plenty of liquid manure when they become pot-bound. Young plants should be stopped several times to encourage a compact habit, always pinching to a bud that will produce a shoot. —T. B. Field.

THE WINTER TREATMENT OF BAMBOOS.

Under the collective and common name of bamboos one includes the three generic names Arundinaria, Bambusa, and Phyllostachys, the species and varieties of which provide us with some most beautiful and ornamental subjects for garden decoration. During the last few years, since the requirements of bamboos have become more generally understood, they have been extensively planted, but there are yet many gardens that might be beautified by their presence.

Although it is an acknowledged fact that they are seen to the best advantage when planted on the margins of streams, lakes, ponds, etc., water is not an absolute necessity, as proved to demonstration in numberless instances. Many have so far excluded them from gardens on the assumption that they are not perfectly hardy, but this is quite a mistaken idea, for if they are planted in positions that are sheltered from cutting north and east winds they will withstand the most severe frost we are likely to experience in this country. Bamboos will succeed on both heavy and light soils, but the ground should be well worked before planting, and an abundance of decayed leaf-mould or farmyard manure incorporated. Although it is not necessary to plant them on the margin of water, they are moisture-loving subjects, and during the warm days of summer abundant supplies of water should be given them.

One frequently sees bamboos in a condition that fails to do them justice owing to the soil not being sufficiently rich for them to make strong growths and fully display their distinctive charms, but this may be easily improved, and no time is more suitable than the present for accomplishing the work. All bamboos appreciate and revel in a rich compost, but do not always find this in the surrounding soil. Therefore, it is necessary to supply their wants artificially. Liquid manure from the farmyard is an excellent agent for soil enrichment, and during the winter months it can be applied in quantity. Even when bamboos are thriving liquid manure can be applied with advantage. Another very good method of assisting them is to take out a trench from two to three feet in depth, at a distance of three to four feet or more, according to the size of the plant, from the stems, so that the principal roots are not damaged. Then fill this with decayed cow manure and loam, or a mixture of leaf-soil and loam, and manure. If cow manure is not obtainable horse droppings will answer the purpose very well, and one will be able to see the good effects in the season following. Good mulchings of decayed manure are also very beneficial, especially if soakings of water are given afterwards.

In many gardens where bamboos are cultivated their flowering propensities sometimes destroy their beauty, but fortunately this occurrence is rare, and need not deter anyone from planting largely. It generally happens that when a bamboo commences to flower in one garden it is heard of as flowering in many others, and when this is the case there is only one remedy, and it is a drastic one. The whole of the plant or clump can be taken out, root and stem, and thrown away, as it will not recover, or so little will be its recovery that it cannot be considered an ornament. This may appear very disastrous to some, but an abundance of seeds can be gathered which germinate freely, and soon make healthy plants. A. E. Thatcher.

Elstree.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

ODONTOGLOSSUM HOUSE.—There can be no doubt that the cultivation of odontoglossums has been materially improved during the past few years in this country. I am of opinion that one of the chief causes of what one might call more successful cultivation is, growers have realised that in the past we have attempted to grow odontoglossums at too low a temperature during the winter months. We have given up attempting to provide what we used to term natural conditions, and have endeavoured to accommodate the plants to suitable treatment, such as can be provided under artificial conditions.

TEMPERATURES. — There can be no doubt that a temperature ranging between 40 and 50 deg., with normal outside conditions, was a mistake. There are few successful growers of odontoglossums to-day who would like to see the temperatures of their odontoglossum houses remaining for any lengthened period below 50 deg., even with severe weather outside. Why the fact was so long overlooked that the majority of the plants in this division are in their most active stage of growth during the winter months is difficult to understand. But now that it is realised it is only natural we should afford odontoglossums the same encouragement as is given plant life generally, when growth is in the most active stage of development. The night temperature at which we keep our plants, with normal outside conditions, is from 53 to 55 degrees. The temperature of the house in which we have been successful in raising and growing seedlings seldom drops below 55 deg. With such temperatures and proper attention to ventilation, we procure changing atmospheric conditions, and these prevent stagnation, such as prevailed with cooler temperatures.

FLOWER SPIKES AND INSECT PESTS.—The flower scapes will now be making their appearance from the base of the recently-developed or developing pseudo-bulbs. Slugs and small shell snails are very plentiful, so that more than ordinary diligence is necessary to prevent the spikes being injured by these pests. Some bran or brewers' grains placed on pieces of broken pots and put about the stages or on the pots where slugs are found to be working, we find make good feeding grounds for these pests, and, with the aid of a light at night and early morning they are easily caught and destroyed. A few lettuce leaves placed about in the same way also form good traps on which to catch and destroy them. A little cotton wool wrapped around the base of the leaf, through which the scapes are advancing, and around the spike itself when more developed, forms an obstacle difficult for them to surmount, and some little protection is thus afforded.

INFLUENCE OF LIGHT.—Where plants are in an advanced state with their flower scapes every encouragement must be afforded them. It is not a question alone to see that the plants are prevented from remaining dry at the roots for any lengthened period. The light is one of the chief factors to be considered at this season of the year. See that the plants are placed in such a position that they may derive the greatest possible benefit from the available light at the present season of the year. Much has been said and written about the want of texture in the flowers. In some cases the texture has been such that the durability and usefulness of odontoglossums for cut flower purposes have been affected. I am not at all surprised at this, when we procure larger pseudo-bulbs and more vigorous growth, unless more light is given, so that the pseudo-bulbs may become properly ripened, we cannot hope to produce high quality of bloom. The same may be applied to all wood in fruit trees or plants in general. We cannot hope to obtain satisfactory results without the advantage of proper maturity.—H. J. Chapman, Oakwood Gardens, Wylam-on-Tyne.

FRUITS UNDER GLASS.

FORCING FIGS IN POTS.—These were in all probability started last month in a pit or suitable house with the pots plunged in a bed of oak leaves and where artificial bottom heat can be given if required. Trees started as suggested will be showing signs of growth. Maintain a steady bottom heat of 65 to 70 deg., and a day temperature of 60 deg. with a rise with sunheat. Renew the plunging material when the heat is declining, as this is better for the trees than artificial heat. On bright days give copious syringing with tepid water, closing the house early. The trees will not require much water at the roots till they are further advanced. If a pit or house is not available for these they may be grown successfully in the vinery if placed therein before or when the house is started. If this be done they should be scrupulously clean. One of the best varieties for forcing is St. John's or Pingo de Mel, but owing to having a white flesh it is not a general favourite, although very sweet and richly flavoured. Violette Sepor is a good one for this purpose, and comes in a short time after the former, if not as soon, especially if the trees are strong. The fruit is of good size, and freely produced, the flesh dark and of good quality. We are discarding St. John's for this variety.

EARLY FIG HOUSE.—The early house in which the figs are planted out may at once be started. The old wood will have been thoroughly cleaned, old soil removed from the surface of the border, and some good loam used for top dressing mixed with mortar rubble. No manure need be given till it can be seen what the crop is likely to be. The wood should not be crowded, and in pruning cut the shoots not required clean out. Roots of fig trees should be restricted to a moderate space, and they should be prevented passing down into the subsoil, for if that happens failure will be the result. See that the border is not dry when the trees are started, syringe well on bright days, especially if the walls are liable to become dry. About 50 deg. at night and from 55 to 60 deg. by day is ample for a start. Brown Turkey, Violet Sepor. Brown Ischia, and Black Ischia are the most suitable for growing in borders under glass.

PEACH AND NECTARINE HOUSE.—The beginning of January is early enough for starting peach-houses to ensure a good crop of fruit and high quality. Small lean-to houses with the border wholly inside are the best for this purpose. Water the border if at all dry, and give the shoots plenty of room when tying them in. These must be started with a very low temperature, say 45 deg. at night and 50 deg. by day, with a rise with sunheat, or the water in the pipes may be warmed and a little air admitted at the same time to effect a change in the air. At the temperature suggested the flowers will soon expand. Fresh clean oak leaves may be used to start them with, and they are better than fire-heat. As soon as the flowers are open a little air should be continually admitted, and sufficient warmth be maintained in the pipes to raise the temperature to 55 or 60 deg. during the day, and 50 deg. during the night. The flowers should be artificially set with a rabbit's-tail, keeping this always dry. The best for early forcing are the true variety of Early Grosse Mignonne peach and Precocé de Croncels nectarine. The second house should be made ready for starting on the first day of next month. If white scale is present this should be destroyed by the careful use of some approved insecticide. Clean the walls and rafters with some strong soapy water. Red spider is one of the most troublesome enemies of peach and nectarines, and old walls should be whitewashed, previously having the crevices filled up with cement. The walls are best cemented all over and painted every spring. Cover outside borders with dry leaves or long litter, and over this lay old lights or corrugated iron. If the trees are of a good age and carry heavy crops, a little artificial manure may be mixed with the soil when top-dressing.

BANANAS.—These require a steady temperature during the winter of 65 deg. at night and from 70 to 75 deg. by day; any sudden fluctuation in the temperature is liable to make them throw up the fruiting crowns—especially if growing in tubs, and intended to produce fruits next summer. As there is very little sun to draw them out the fruit will be short and stumpy. Watering should also be done carefully, they should be neither too wet nor too dry. If the soil become at all sour sprinkle a little slaked lime on the surface at intervals until such times as they can be overhauled. Those planted out are preferable to those grown in tubs, being easier of cultivation, and better fruits are obtained. Any that are ripening off their fruits should be kept on the dry side. A few of the strongest suckers in No. 1 pots will be ready for tubbing next month. Frequent fumigations will be required to keep down black-fly.—A. B. Wadds, Paddockhirst Gardens, Sussex.

THE KITCHEN GARDEN.

SEAKALE.—The crowns required for forcing should now be lifted, and all the best thongs cut into lengths of about five inches, with the cut at the top quite straight, and at the lower end in a slanting direction. Tie them in neat bundles, and bury them in soil to keep them from shrinking. Where quantities of forced vegetables are required a batch of crowns must be placed in heat every fortnight. Plant them in beds of 50 or 100 in each, according to the demand. If nine or ten roots are put in ten-inch pots, with inverted pots over them to exclude the light, they can be removed either into more heat or retarded, as may be found the most desirable. A good position for the bed in which crowns are planted is on the lower stage of the mushroom house. Place a sack or mat in front to keep the draughts from the tender growth, and keep the roots fairly moist until the seakale is ready for cutting.

FRENCH BEANS are always appreciated in the dining-room, especially if they are gathered before they become old and stringy. Osborn's Early Forcing is a most reliable variety for early supplies, as also is Reliance. The seeds should be sown in six-inch pots, at this early period, as they will be able to take more stimulants than those occupying larger pots, when the flowers have set. Good drainage, and a compost consisting of light loam, leaf-soil, and old spent mushroom bed manure are desirable. Place eight or nine beans in each pot, and should they all germinate two or three plants can be drawn out. If the soil is moderately moist they will not require watering until the plants are well up, when they may have a soaking of tepid water. They must be near the glass, and have a temperature of from 60 to 65 degrees.

HORSERADISH.—Beds of horseradish that have been in the same position for several years should be taken up. The roots should be assorted, and small straight roots, nine or ten inches long, be selected for replanting. In preparing these take out all side rootlets and eyes, and replant in deeply trenched ground. Deep holes should be made with a crowbar in rows half a yard wide, and a foot apart, from each hole, and the cuttings dropped in as the work proceeds. Lay in some of the best and thickest pieces for present use, so that the permanent bed may not be disturbed for several months.

CAULIFLOWERS.—A small sowing of seed of these should now be made, varieties such as Sutton's First Crop and Early London being the most serviceable. Keep the seedlings close to the glass, and rather cool. Also sow a pinch of seed of Brussels sprouts and cabbage, and treat the same way.—T. W. Birkenshaw, Hatley Park Gardens, Sandy.

BEST PLANTS FOR GREENHOUSE.—Nearly 300 pages are devoted to the description, propagation, and culture of the best flowers and plants for the greenhouse in The Amateur's Greenhouse, price 5s. net. or by post 5s. 6d., from The Gardeners' Magazine Office, 148, Aldersgate Street, London.

SEED AND SOIL INOCULATION.

In a neat brochure of some thirty pages Professor Bottomley, of King's College, London, gives a highly interesting account of the experimental work in connection with the nitrogen-fixing organism of the legumes, to which he has devoted much time and attention during the past two years. After a brief reference to the essential elements of food necessary for the development of the plant, Professor Bottomley directs attention to the more important of the elements present in soils, and to the necessity of nitrogen as an element of plant food and to its abundance in the atmosphere.

With reference to the desirability of utilising as far as possible the supplies of atmospheric nitrogen, Professor Bottomley writes:

"What is wanted is a cheap supply, and modern science has revealed this by showing the ability of leguminous plants, when in association with certain bacteria, to utilise the inexhaustible store of atmospheric nitrogen, and add large quantities of combined nitrogen to the soil.

"It has been calculated that there are about 75,000,000 pounds of atmospheric nitrogen above every acre of land of the earth's surface. Taking the value of nitrate of soda, containing 16 per cent. of nitrogen, at eight shillings per 100 pounds, the commercial value of one pound of nitrogen would be sixpence. At this valuation there is nearly £2,000,000 worth of nitrogen above every acre of land, free and waiting to be utilised!

"How can it be done? Well, Nature has revealed to us the way, and shows how by means of those wonder working agents of hers—bacteria—it is possible to obtain practically unlimited quantities of nitrogen from the air for the use of farm crops, at a very small cost. These bacteria live in the nodules or tubercles which are found upon the roots of all leguminous plants (peas, beans, clover, lucerne, etc.). There they multiply and absorb the free nitrogen from the air, and cause it to unite with other elements to form compounds which are suitable for plant food."

The work of the scientists who have during the past twenty or more years been engaged in the investigation of the nitrogen-fixing organism is passed under review. Among the scientists associated with this line of research are Hellriegel, who demonstrated that leguminous plants obtain their nitrogen from the air, and that their growth in soil free from nitrogen compounds depends upon nodules upon their roots; Professor Marshall Ward, who traced the development of the tubercles from the infection of the root hairs of plants by some organism in the soil, up to the formation of the mature nodule, and showed that the tubercles could be produced by the inoculation of roots with bacterial infusions; Beyerinck, who obtained a pure culture of the root-tubercle organism on artificial media and named it Bacillus radicicola; Prazmowski, who succeeded in inoculating the roots of bean plants growing in sterilised soils, and obtaining luxuriant growth by watering the plants with a liquid culture of the organism; and Professor Nobbe, who was the first to attempt the inoculation of soils by means of pure cultures on a large scale. These cultures were prepared and sold under the trade name of Nitragin, as our readers have been fully informed. In some cases satisfactory results were obtained, but the failures being so numerous the manufacture of the cultures was given up. Professor Nobbe's principal of inoculation was sound but had not devised the correct method of application.

Seven years since the United States Department of Agriculture commenced "a scientific investigation of the root-nodule organism, with a view to making it practicable for use in the United States, the pure method of inoculation." In the course of this it was discovered why Professor Nobbe's methods of culture were so uncertain in their results; and the cause of this uncertainty is explained by Professor Bottomley. Improved methods of culture were worked out by the American scientists, and the results obtained during 1901 and 1902 were such as to induce the United States Government to distribute the inoculating material on a large scale. In 1903 and 1904 over 12,000 packages were sent out free to farmers and others and, according to the report published at the beginning of 1905, 74 per cent. of the trials were successful.

The report of the results attracted much attention in this country as well as on the other side of the Atlantic, and in 1905 the Board of Agriculture "obtained the co-operation of thirteen different agricultural colleges and experimental stations, with a view of testing the cultures." According to the official report, the negative results exceeded the positive in number, but some of the latter were so striking as to fully justify further trials. The Board of Agriculture did not, however, proceed further with the matter. After referring to the apathy of the Government, which it is suggested ought to have recognised the fact that the matter was of national importance, and provided the necessary funds and machinery for a thorough investigation, Professor Bottomley proceeds to describe his own work in the preparation and distribution of pure cultures of the nitrogen-fixing organism, and the conditions most favourable to successful inoculation; and, as indicating its scope, we give a few extracts:—

"During the winter of 1905, research work on some unsolved problems in the life-history of the nitrogen-fixing organism had been in progress at the Botanical Laboratory, King's College, London, and the experiments of the Board of Agriculture had been followed with keen interest. In the spring of 1906, when it was found that the Board did not intend to follow the subject further, much disappointment was felt, and eventually, after considerable hesitancy, it was decided to distribute such of the pure cultures from the King's College experiments as were suitable and available for inoculation, and thus continue within the narrow limits of time and means at disposal, the work which ought to have been carried out by the Board of Agriculture.

"In the autumn of 1905 a bulletin had been published by the New York State Experiment Station showing the inability of the nitrogen-fixing organism to retain its vitality for any considerable time when dried on cotton wool—from six weeks to two months being the limit in most cases. Failure followed each attempt to develop cultures of the organism from the commercial cotton cultures. These failures could not be ascribed to the laboratory methods employed, since the method was uniformly successful when laboratory cultures of the organism were used in the place of cotton cultures. The failure of these cultures was due to 'the inability of the nitrogen-fixing organism, under ordinary atmospheric condition, to maintain itself upon the cotton for any considerable time. While our results explain the many failures from the use of cotton cultures, they should not be understood as being opposed to the idea of treating the seed of legumes with living bacteria.' Little wonder that the Board of Agriculture obtained so many negative results when in their report we find it stated 'that in some cases the cultures were received from Washington in the autumn of 1904, but were not used till the following spring.' In this connection it is interesting to note that the American Government has given up the use of cotton wool as a medium for distribution, and now sends out the pure cultures in liquid form in bottles.

"When it was decided to send out inoculating material from the Botanical Laboratory at King's College, it was necessary, in view of the New York experiments, to find some other medium than cotton wool for distribution of the pure cultures. After a number of experiments it was found possible to obtain a powder preparation of the bacteria, in which condition they retain their vitality for months. Some are still active after being kept for two years.

"During 1906 and 1907 over a thousand packages of this preparation have been distributed free to any one who cared to test inoculation of seed or soil, with the gratifying result that over 80 per cent. of the reports returned show an increase of crop from its use.

"At this point it will be well to utter a warning against any misconception or unjustifiable expectations regarding the use of bacterial cultures. Inoculation is not a panacea for all soil ills. The cultures are not a manure, they simply add to the soil the nitrogen-fixing bacteria which are essential for the most successful growing of leguminous crops, and this only when certain soil conditions are favourable.

"To begin with, it should be clearly understood that the nodule-forming bacteria supply nitrogen only to the crops and soil. If the land is deficient in phosphates, potash, or lime, these must be added if the bacteria are to do their work properly. Plants require phosphates, potash and lime, as well as nitrogen, for healthy and vigorous growth, but nitrogen is the most important as well as most expensive food element, and given the presence of the other food elements in the soil, inoculation will supply all the nitrogen necessary for the luxuriant growth of a leguminous crop, even in such an unlikely medium as sterilised sand. A fine crop of Mexican beans has been grown in volcanic ash from Guatemala in King's College laboratory by simply adding culture solution to the ash.

"Cinders can hardly be considered an ideal soil, yet an experimenter reports 'We also sowed inoculated sweet peas on a cinder path at the top of a low wall, and they have grown and blossomed very freely, and looked very nice hanging over and covering the wall. Our friends have been quite astonished to see them growing in cinders.'

"Another point to be remembered concerning inoculation is that soils rich in available nitrogen do not respond to inoculation. Where plants can obtain nitrates from the soil they appear to prefer this source of nitrogen supply, and tubercle formation is prevented. The fact that tubercles are not found in any quantity upon plants growing in rich soils has been frequently observed. Prof. Vines demonstrated some years ago that the presence of nitrates in the soil has an unfavourable effect upon the nitrogen-fixing bacteria, and that there is a definite relation between the amount of nitrates present and the number of root-nodules. He states 'The results of all these experiments agree in showing that the development of tubercles is much less when nitrate is present in the soil than when it is absent. It is also indicated that as the amount of nitrate diminishes, the development of tubercles becomes more marked. In all cases in which tubercles made their appearance on the roots of plants which had been supplied with nitrate, they are exclusively developed on the youngest roots, especially on those near the surface of the sand; in that part of the soil, which would naturally lose its nitrates most rapidly.

"It cannot be too strongly emphasised that the cultures of nitrogen-fixing bacteria are not to be regarded in the light of nitrogenous fertilisers, increasing the yield under any or all conditions. The cultures do not contain nitrogen. They simply add to the soil the bacteria which, under favourable conditions, form nodules on leguminous plants, and render available the nitrogen from the atmosphere for the growth of these plants. As already pointed out, rich soil containing plenty of available nitrogen checks the activities of the bacteria. It is poor soil which responds most readily and liberally to inoculation; the thousands of acres of non-productive land it does not pay at present to till and manure, which can be restored to fertility and productiveness by the use of these bacteria cultures.

"What, then, are the conditions under which a cultivator may expect to benefit by inoculation? Inoculation is necessary when the land is poor or 'thin,' that is, low in organic matter, and has not recently borne a leguminous crop.or when the roots of legumes grown are devoid of nodules. Inoculation is desirable when a different leguminous crop from that previously grown on the land is being planted; or when the crop growing, though possessing root nodules, is not producing up to the average. The introduction into the soil of a more virulent race of bacteria may greatly increase the yield.

"Inoculation is useless when the legumes usually grown are producing high yields, and the roots show nodules in abundance; or when the soil is rich in available nitrogen, for under this condition few nodules would be formed.

"Given suitable conditions the advantages which may be expected from inoculation are:

"1. Increased yield of leguminous crop.

"2. Improvement of land for succeeding crops, by adding organic nitrogen to the soil.

"3. Increase of nitrogenous contents of inoculated plants, which means increase of feeding value.

"4. In many cases hastened maturing of plants, thus allowing of earlier marketing of produce with enhanced value.

"Increased Yield.—The amount of increase will naturally vary according to differing conditions, and it is evident from what has been already stated that the greatest increase may be expected on poor or worn-out soils. As regards the soils of this country, it is often said that 'they are too good to respond to or need inoculation.' One writer recently stated that 'ninety-nine per cent. of our soils have all the microbes they need.' But the results given on pages 16 to 29 (of the brochure) show how erroneous such statements as these are.

"Increase of Fertility of Soil.—That leguminous crops effect a marked benefit on the yield of succeeding crops is so well known, that it is the practice of every farmer who wishes to maintain the fertility of his soil to include some leguminous crop in his rotation of crops. It can easily be demonstrated that the greater part of this benefit is due to the organic nitrogen supplied by the root-nodules, and that unless the nodules are present the leguminous crop actually exhausts the soil instead of improving it. It has already been pointed out that the nodules are the centres of nitrogen-fixation. In their tissues are stored up quantities of organic nitrogen greatly in excess of what is required by the leguminous plant. When the crop is harvested these nodules remain in the ground, and the nitrogen store of the soil is correspondingly increased.

"Increase of Feeding Value of Crop.—It sometimes happens in inoculation experiments that there is no evident difference in the yield from inoculated and non-inoculated plots. Now a visual comparison is apt to be misleading, and the only accurate way of obtaining results is by weighing the produce. This is well seen in the report from Grappenhall, where a crop that showed no appreciable difference to the eye weighed 30 per cent. more than the non-inoculated.

"Early Maturing of Crop.—A striking fact brought out by the experiments during the last two years is that, in a number of cases, inoculation has hastened the maturing of the crop very materially. Reference to the reports shows that 'ten days,' 'a fortnight,' and 'three weeks' are given for earlier ripening of inoculated crop. With early crops this means earlier marketing and enhanced prices, a matter of the greatest importance to growers.

These extracts will serve to show the importance of what has been already accomplished by Professor Bottomley, and that the results of the experiments which have been made in various parts of the United Kingdom have been such as to justify an extension of experimental work on a much larger scale than has hitherto been the case. It is shown that the inoculation of soil for leguminous plants is by no means costly, as "one gallon of culture solution will inoculate seed for twelve to fifteen acres of land, and when diluted will, when sprayed or watered on the soil, suffice for an acre or more." The cost of sufficient of the pure cultures for making a gallon of solution is about 3s.

For the preparation and application of the culture solution, and for the reports on the experiments that have been made during the past two years, we must refer our readers to Professor Bottomley's brochure, which is published at "Country Life" Office, Tavistock Street, W.C., the price being one shilling. It should be carefully read by all who are engaged in the production of garden and farm crops.

JUBILEE of the GRAND YORKSHIRE GALA AT YORK.
JUNE 17, 18, and 19, 1908.
ONE THOUSAND GUINEAS IN PRIZES.
For Schedules, apply to
FRED. AREY, Davyhall Chambers, York.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY. Under Gardeners. Profitable Winter evenings. Plan competition. For particulars, apply to P. MURRAY THOMSON, Secretary, Royal Caledonian Horticultural Society, Edinburgh. 1908 Spring Show, 15th and 16th April.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at ninepence per line, the minimum charge being Five Shillings. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Royal Horticultural Society.

JANUARY 14.

The exhibition on the above date was one of the smallest held in the hall for a very long time—perhaps the smallest. In one sense the meeting was a record one—in that the Floral Committee had not a single novelty placed before it. Within the memory of the oldest committee man there had never before been a clean sheet. Winter-flowering plants were the feature of the meeting.

In the afternoon Mr. J. Gregory displayed a most interesting series of lantern slides in the Lecture Hall, showing the leading exhibits arranged at the Temple, Holland House, and other shows during the year.

FLORAL COMMITTEE.

The display of winter-flowering plants made by Messrs. James Veitch and Sons, Chelsea, was a success and on this occasion, when exhibits were few, it was all the more interesting and instructive. The big group included batches of lily of the valley, freesias, Jacobinia coccinia, J. chrysostephana, forced azaleas, Calceolaria Burbidgei, Moschosma riparia, cyclamens, Leonotus Leonurus, oranges in flower and fruit, the pretty Citrus myrtifolia, and Roman hyacinths.

Messrs. William Cutbush and Son, Highgate, were extensive exhibitors, and helped to save the situation. They had hellebores, Hamamelis arborea, Daphne mezereum, Adonis Kihusaki, A. amurensis, Iris tauri, I. histris, I. histrioides, Sternbergia hyemalis, retarded Lilium speciosum, L. longiflorum, and L. auratum, camellias, heaths, spiræas, etc., and a collection of winter-flowering carnations, including a dozen blooms of Marmion that were shown at the previous meeting.

Buddleia asiatica was largely shown by Mr. L. R. Russell, Richmond, Surrey; this is a very useful winter-flowering greenhouse plant. This was associated with berried aucubas, variegated euryas, ivies, euonymus, etc. Messrs. Hugh Low and Co., Bush Hill Park, Enfield, contributed quite a large and pretty display of perpetual-flowering carnations, setting up good flowers of such varieties as Robert Craig, Nelson Fisher, Mrs. T. W. Lawson, Lady Bountiful, Mrs. Burnett, Harlowarden, Enchantress, Pink Enchantress, White Enchantress, etc., in tall, clear glass vases, in a most effective manner. The same firm arranged a group of Eurya latifolia variegata, edged with Aralia Sieboldi.

Christmas roses and pernettyas were exhibited by the Misses Hopkins, Mere, Shepperton, the former very clean and good. Messrs. John Peed and Son, West Norwood, contributed an exhibit of saxifragas and other alpines in pans, and a small collection of cacti.

ORCHID COMMITTEE.

Messrs. Charlesworth and Co., Heaton, Bradford, showed Odontoglossum crispum Lyott, a heavily and richly-marked variety, and Cypripedium Fowlerianum. Mr. Whitelegge, gardener to J. Bradshaw, Esq., The Grange, Southgate, showed Odontoglossum venustulum Apollo and Lycaste Skinneri armeriaca. Messrs. Sander and Sons, St. Albans, brought up Odontoglossum MacNabiana (F.C.C.), a large-flowered, handsome hybrid between O. Harryanum and O. Wilckeanum albens; this has heavy chocolate and red-brown markings on a yellowish ground, and a white, yellow, and red marked lip. The purple tips to the petals are also an additional attraction. Mr. H. Little, Baronshalt, Twickenham, showed a fine five-flowered spike of L.-c. callistoglossa ignescens. Messrs. J. and A. McBean, Cooksbridge, submitted Cypripedium Minos Youngi (F.C.C.), a splendid form, with broad white and green dorsal sepal, and brownish-green sepals and petals.

From Westonbirt, Mr. Alexander, orchid grower to Major Holford, brought up Cypripedium Sultan (F.C.C.), a bold cross between C. Mons. de Curte and C. Milo Westonbirt var.; it has broad bright brown petals, with greenish ground and edges, brown lip, and green and white dorsal sepal, the latter heavily spotted with dark purple over the green area; also from Westonbirt came L. c. Corunna, a neat purple hybrid of unknown parentage.

Messrs. Armstrong and Brown, Tunbridge Wells, showed Cypripedium Maudiæ, C. Helen II., C. Muriel Hollington var. albescens, and C. Helen Armstrongæ—a pretty set. Mr. H. Ballantine, gardener to Baron Schroder, The Dell, Egham, showed Odontoglossum Bingelianum (F.C.C.), a beautiful hybrid, with large finely-formed flowers of soft greenish-yellow ground colour, heavily blotched and spotted with brown; the lip has a white apex and red basal marks.

A very small group of cypripediums was contributed by Messrs. Heath and Son, Cheltenham; this included varieties of C. insigne and C. Leeanum, Cattleya Percivaliana, and a curious hybrid between C. Walkeriana and C. Loddegesi. Messrs. Hugh Low and Co., Bush Hill Park, Enfield, sent up Cypripedium insigne Lucieni, C. Leeanum Clinkaberryanum, C. aureum virginale, C. Mrs. W. Mostyn, C. Thompsoni, and C. Euryades var.

FRUIT COMMITTEE.

Messrs. H. Cannell and Sons, Swanley, Kent, set up a very interesting collection of Kentish-grown apples, in which about one hundred varieties were represented, many of them in very fine style. The baskets of Bramley's Seedling, Beauty of Kent, Mere de Menage, Annie Elizabeth, Lane's Prince Albert, Cox's Pomona, Gascoigne's Scarlet, The Queen, Warner's King, Peasgood's Nonsuch, Emperor Alexander, Striped Beaufin, Allington Pippin, Charles Ross, and Lord Derby were particularly good.

Miss C. E. Martin, Willowbrook, Auburn, N.Y., showed a collection of bottles of fruit in great variety. All the fruits appeared to be in excellent condition, and all were in glass bottles. The peaches, pears, strawberries, and cherries were all preserved in brandy.

CERTIFICATES AND AWARDS.

First Class Certificate.—Odontoglossum MacNabianum, from Messrs. Sander and Sons, St. Albans; O. Bingelianum, from Mr. H. Ballantine, gardener to Baron Schroder, The Dell, Egham; Cypripedium Sultan, from Mr. Alexander, orchid grower to Major Holford, Westonbirt, Gloucester; and C. Minos Youngi, from Messrs. J. and A. McBean, Cooksbridge.

Award of Merit.—To Lælio-cattleya Corunna, from Major Holford.

MEDALS.

Silver-gilt Knightian.—Messrs. H. Cannell and Sons, Swanley.

Silver-gilt Flora.—Messrs. William Cutbush and Sons, Highgate; Messrs. H. Low and Co., Bush Hill Park, Enfield.

Silver-gilt Banksian.—Messrs. J. Veitch and Sons, Chelsea.

Silver Banksian.—Messrs. J. Peed and Son, West Norwood; Mr. J. R. Russell, Richmond; Messrs. Hugh Low and Co., Enfield (orchids); Messrs. Heath and Son, Cheltenham; and Miss Martin, Willowfield, Auburn, New York.

Cardiff Gardeners' Association.

The first meeting in the New Year of the Cardiff Gardeners' Association was held on the 7th inst., at the Philharmonic Restaurant, Mr. H. R. Farmer presiding. The lecturer for the evening was Mr. Harold Evans, The Hardy Plant Nursery, Llanishen, who gave an interesting lecture on the water garden, which subject he divided into two parts—firstly, plants that live entirely in water, and, secondly, moisture-loving plants, trees, and shrubs, some of which he considered were very effective during the winter months, the various colours of the willows and the red dogwood being specially mentioned. The lecturer included in the first part of his lecture references to a large number of nymphæas, and he gave advice on the depth at which they should be planted in the water, and other essential details. Many of the beautiful moisture-loving plants also had attention directed to them. Mr. Graham opened the debate, and congratulated the lecturer on his interesting paper, several members taking part in the discussion that followed. At the close of the discussion it was proposed by Mr. Julian, and seconded by Mr. Toy, that the best thanks of the meeting be accorded Mr. Evans. Mr. J. Prosser was awarded first prize for cyclamen.

Royal Caledonian Horticultural Society.

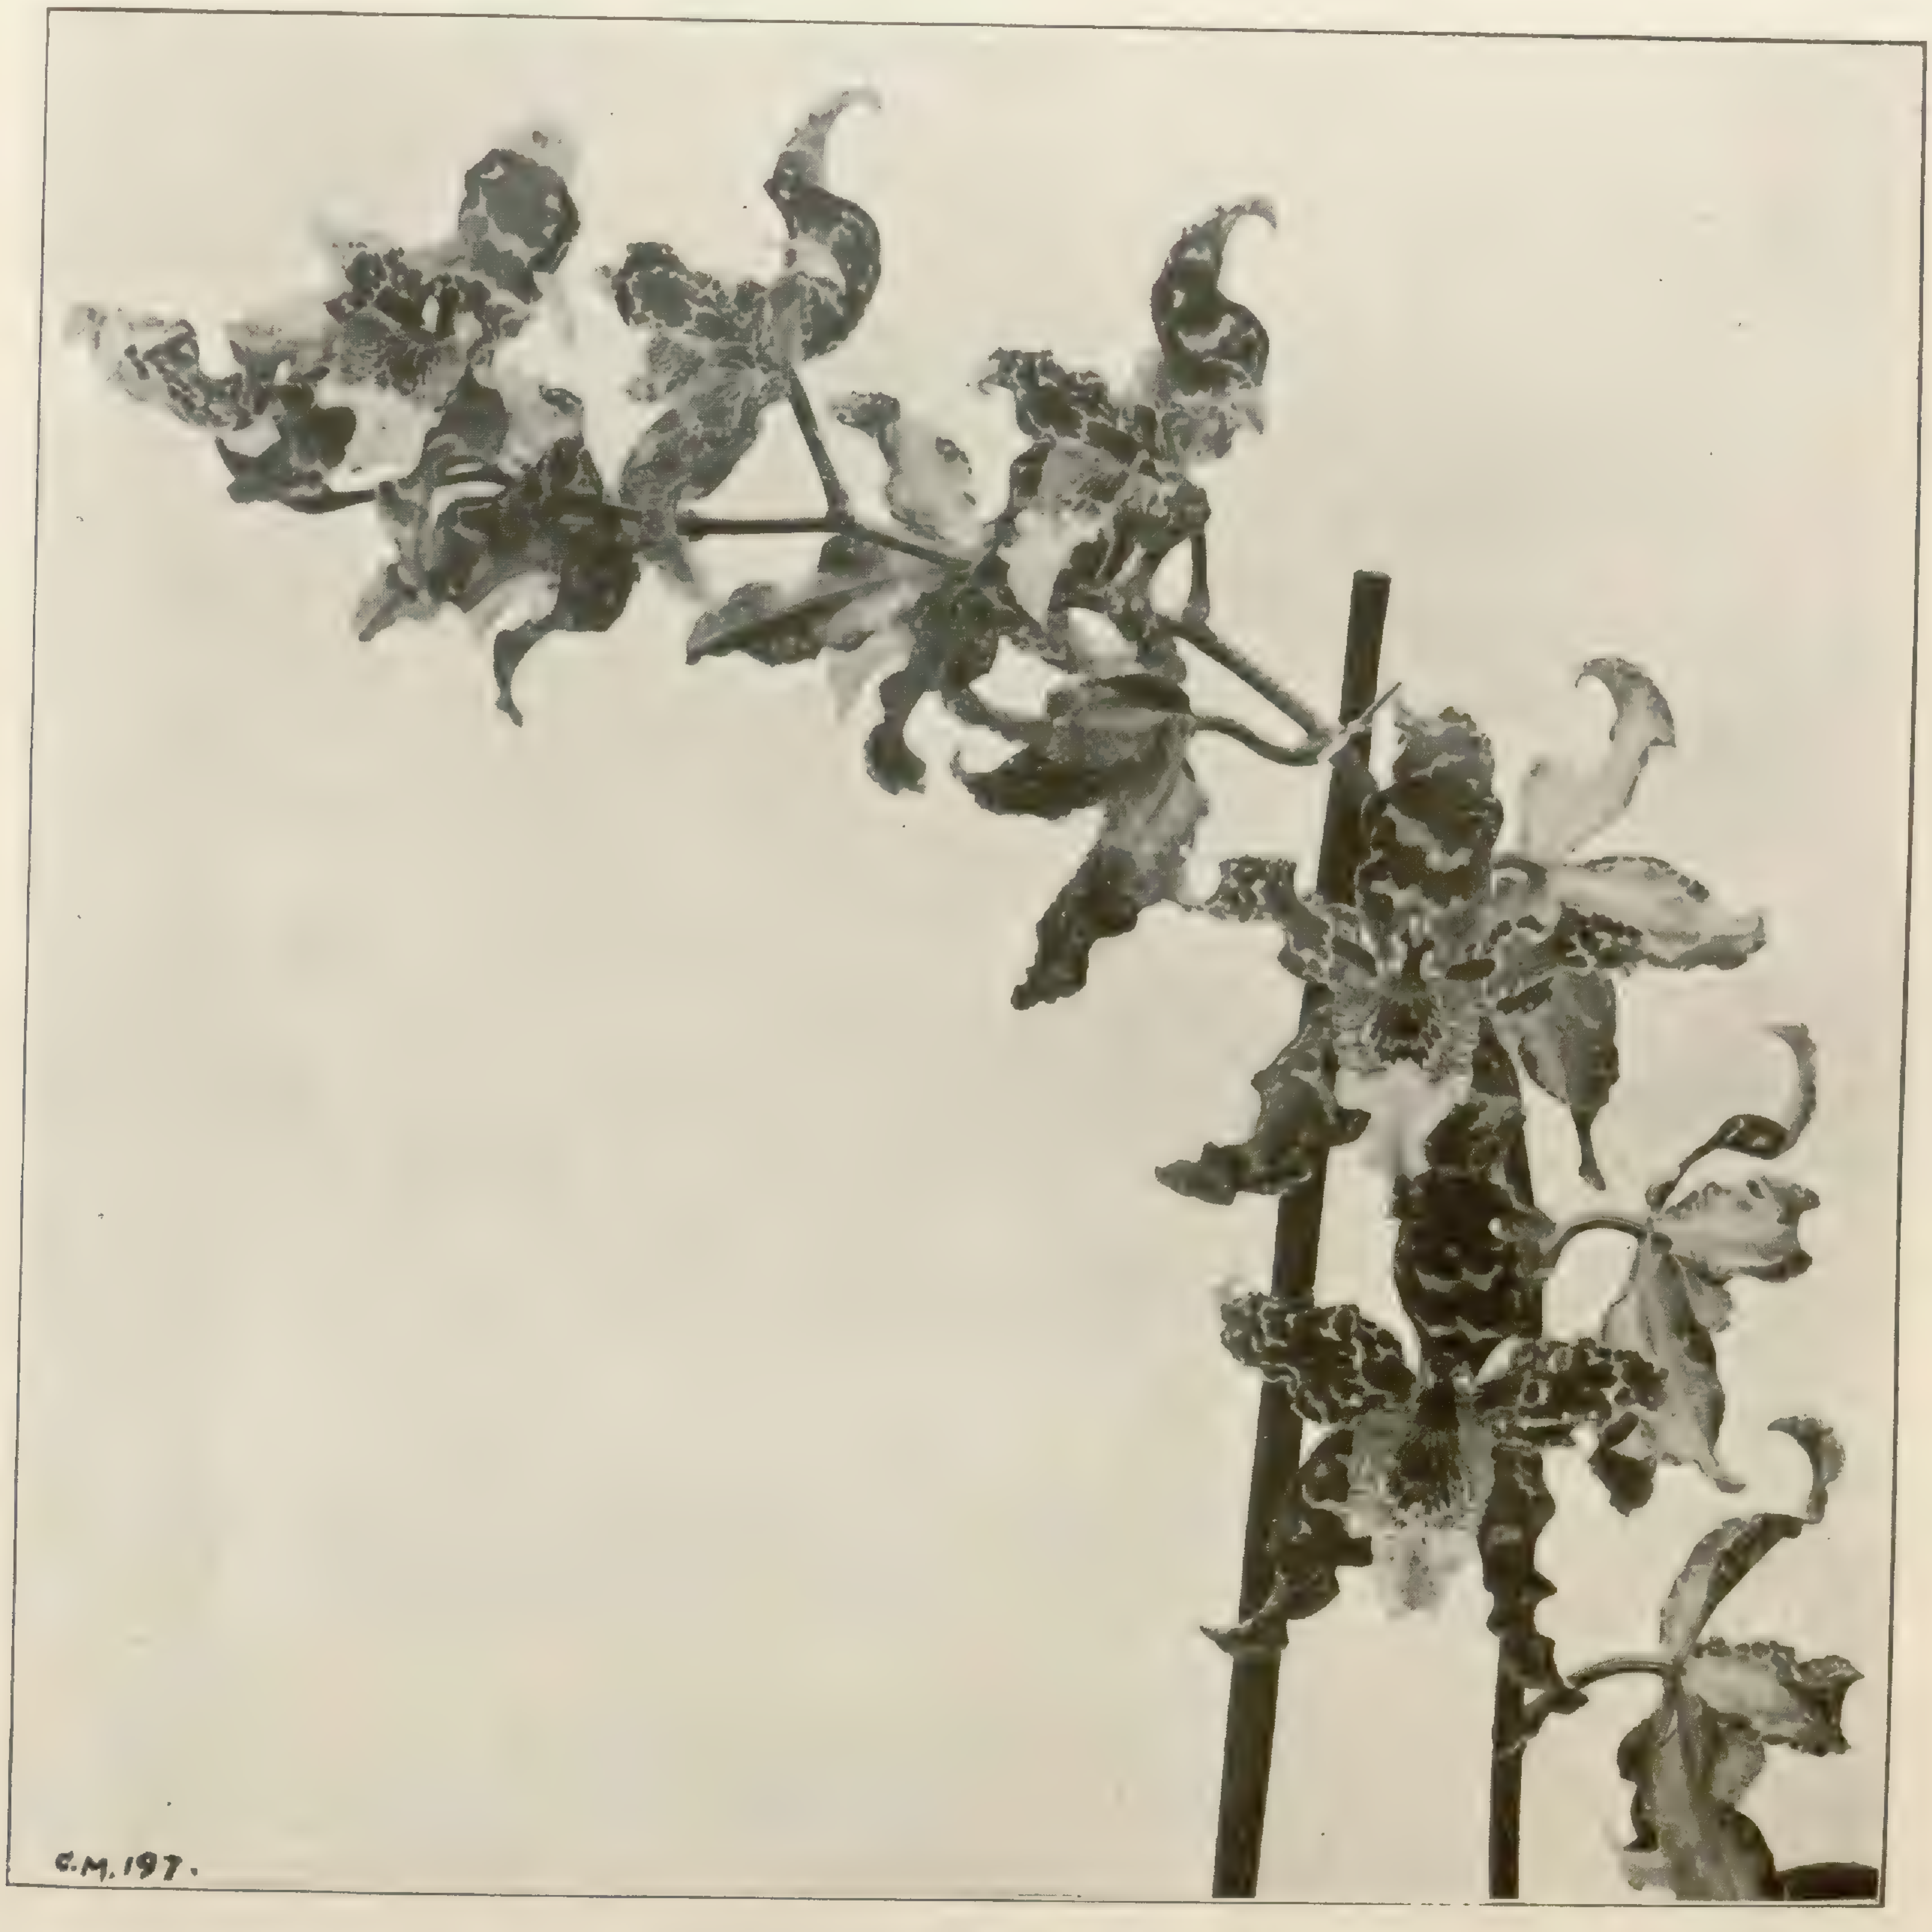
The annual meeting of this society was held a few days since in Dowell's Rooms, Edinburgh, with Mr. W. H. Massie, vice-president, in the chair. After the minutes of the previous annual meeting had been disposed of,

The report for the year was submitted, and this, we are glad to state, was of most satisfactory character. The exhibitions had been highly successful in every way. The competition had been keen, the products generally of a high order of merit, and the attendance had been good. The funds of the society, it was stated, now amount to £1,152, an increase of £93 on the previous year. Reference was made to the resignation of Mr. P. Murray Thomson, and the council stated that they regard his removal as a great loss to the society. He had been an ideal secretary, combining, as he did, the qualities of a good business man with a keen love for horticulture and an expert knowledge of some of its branches. It was considered that much of the success of the society in recent years was due to Mr. Murray Thomson's untiring and solicitous care of its affairs.

The following extract from the minute book was given: "The council desire to minute the sincere regret with which they have received the resignation of Mr. Murray Thomson, and to place on record their high appreciation of the ability and fidelity with which he has for ten years served the society as secretary and treasurer."

The Chairman, in moving the adoption of the report, congratulated the members on the success that had been achieved during the year. They might not have accomplished all they could have wished, but they had done much good work, and the financial results had been of a gratifying character. He alluded to the number of deaths and resignations, and expressed the hope that the members would do their best to increase the membership.

The report having been adopted, the election of office bearers was proceeded with. Lord Balfour of Burleigh was re-elected president, and Mr. J. W. M'Hattie was elected one of the vice-presidents. Mr. John Alex-



ODONTOGLOSSUM MACNABIANA.

Exhibited by Messrs. Sander and Sons, at R.H.S. meeting on Tuesday last, when a First Class Certificate was conferred upon it. Flowers much reduced; the colours, chocolate, red-brown, yellow, and purple.

ander, The Gardens, Niddry; Mr. D. W. Thomson, nurseryman, Edinburgh; and Mr. Gordon Caldwell, Duddingston Cottage, Portobello, were elected to the council in the place of those retiring. Mr. Donald Mackenzie, of Messrs. Henderson and Mackenzie, S.S.C., Rutland Square, Edinburgh, was elected secretary, in succession to Mr. Murray Thomson, who had retired owing to his leaving Edinburgh. The latter, in acknowledging the reference that had been made to his work, said what he had been able to do for the society had been pleasant, and he was glad to think that though they had had ups and downs, he had remained on the most friendly terms with all. He was not going so far away but that he would be able to come to their shows this year, and he would be glad to give any assistance he could to the new secretary.

East Anglian Horticultural Club.

Although not so strong, numerically, in attendance as at former dinners, there were close upon 70 members present at the annual dinner, held at the Boar's Head, Norwich, on January 8. Mr. J. Powley presided, and Mr. T. B. Field was in the vice-chair, supported by prominent local horticulturists. Short speeches upon the toasts of various gardening bodies, and some well-rendered songs, enabled those present to spend a happy evening.

Beckenham Horticultural Society.

At a recent meeting of the above society Mr. Cecil Hooper, F.R.H.S., of Sevenoaks, gave a highly instructive lecture on "Birds in Relation to the Garden," using a fine set of lantern slides for illustrating his remarks. Mr. G. N. Hooper, of Beckenham, occupied the chair, and there was a good attendance, and a profitable discussion followed. Hearty votes of thanks were accorded both lecturer and chairman.

Sandhurst Gardeners' Association.

The fortnightly meeting of this association was held in the Church Schools, Sandhurst, on January 7. There was a good attendance of members, and Mr. J. Evans occupied the chair. The lecture for the evening was, "Some of Nature's Methods of Securing Cross Fertilisation in Plants," by the Rev. H. P. Fitzgerald, of Crowthorne, who dealt with the subject in a very interesting and instructive manner. A series of lantern slides was shown of various flowers, and the way they are fertilised by the wind, bees, moths, and other insects. The lecturer was heartily thanked for his lecture. Mr. W. H. Chapman, Hilfield Gardens, Yateley, staged plants of Primula obconica.

National Chrysanthemum Society.

A fairly well attended meeting of the society's committee was held at Carr's Restaurant, Strand, on Monday, January 13, Mr. T. Bevan presiding.

The chief business was the discussion of the annual report and financial statement, to be presented to the forthcoming annual meeting on February 3. It appears that all payments have been made, but this has necessitated a heavy draft on the reserve fund. Several motions were brought forward for the reduction of expenditure during the present year, and these were adopted. Several new members were elected, and some promises of handsome donations towards the prize fund were received.

Weybridge Exhibitions. — The Weybridge Horticultural Society will hold its summer exhibition on July 9, and its autumn show on November 4. The president for the year is J. Lyle, Esq.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "End-leigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

SCHEDULE. — W. H., Yeovil: Many thanks; we shall be very glad to receive schedule and notices in due course. You have done very well indeed.

PERPETUAL - FLOWERING CARNATIONS.—M. C. N., Putney: The best work is Mr. M. Allwood's "Perpetual-flowering Carnations," published by Messrs. Hugh Low and Co., Bush Hill Park, Enfield. The price is 2s. 2d., post free.

VALLOTA PURPUREA MAGNIFICA.—M. J. P., Leigh: You had better write to the leading nurserymen who advertise in our columns, particularly those who make a special feature of indoor plants; they will quickly let you know if they have the variety, or whether they can procure it for you.

HARD-CENTRED CELERY.—J. H., Cambridge: We cannot tell the cause without an opportunity of inspecting a specimen. Sometimes, when celery has experienced a check, especially such as is caused by lack of moisture, the plants prematurely run to seed, or attempt to do so, and when this happens the centre consists of an elongated stem instead of the usual and much-prized "heart."

STREPTOSOLEN JAMESONI.—C., Isle of Wight: The plants should have been kept moderately dry during the last few weeks. If they have had this rest they may now be lightly pruned and placed in a warm greenhouse. There is no need to provide great heat, neither is this desirable. Syringe the plants occasionally to induce free growth from all parts. In March and April insert a few cuttings.

ASPARAGUS. — E. K., Keighley: We are not acquainted with the variety you name, and therefore cannot offer any opinion as to its merit. If, however, the lady of the house considers Connover's Colossal has the finest flavour when served at table, and the master of the house finds no difference between it and the new variety, it seems to us the better plan would be to plant Connover's Colossal, and none other. If it is possible to do so we should like to have the opportunity of testing the flavour of the new variety in due course.

FLOWERS ON A VINE BORDER.—M. J., Ripon.—If the border is a small one, properly cared for in the matter of mulching, watering, and protection, there will be no opportunity for cultivating flowers upon it. If the border is a very wide one, and we know many such, the front portion may be used for annual flowers, but not for perennials. The most profitable proceeding would be that of thoroughly renovating the old vines or removing them and planting strong young ones. However, if this is not possible, and flowers are preferred to first-class grapes, then annual flowers of moderate growth may be grown on the borders. Watering and supplies of liquid manure will be matters not to be lightly regarded if the season is a warm and rather dry one.

OLD PELARGONIUMS IN BOXES. G. B., Rugby: If you have a fairly well heated pit there should be no difficulty in increasing your stock of pelargoniums by inserting cuttings at once, taking the latter from the old plants. Damping must be avoided, consequently light sandy soil and ample drainage must be provided. The work should commence at once. Gradually harden off the plants after they are well rooted and grow them on a shelf in a warm greenhouse, near the light. If carefully attended to these will be very useful plants for bedding, though not so large as those from autumn-struck cuttings. The cuttings that were placed in boxes last autumn must soon be carefully potted up, otherwise they will be starved, and make weakly growth.

STANDARDS OF CALCEOLARIA AMPLEXICAULIS.—H. A., Runcorn: For large beds in the flower garden the use of standard specimens of Calceolaria amplexicaulis has much to recommend it. These plants are readily produced by inserting cuttings in cold frames in autumn and potting these up early the middle of the following April. Grown in an intermediate house they will rapidly extend, and should have all side growths removed until six inches short of the desired height is reached. Then pinch out the growing point, and pinch out the tips of subsequent growths until sufficient branches are formed to produce a good head. Growth is rapid, and with careful attention to watering, etc., it is possible to obtain good heads by planting out time, in June.

CHRYSANTHEMUM SHOW REGULATIONS. — J. S. R., Bucks: We sympathise with you, but unless we have the whole facts of the case before us, from either side, we cannot publish your letter. Every officer should do his best to see that the rules and regulations of his society are carried out fearlessly, and should also help in carrying them out. A secretary is often overburdened with work on show day, and, therefore, unless a protest is handed in at the proper time, and in the proper manner, the person protesting may not receive the consideration and justice that may be due to him. Quite often have we seen a protesting exhibitor firing off his protest in an excited and voluble manner, and waxing indignant when told to put his protest in writing, "according to rule." Such an exhibitor is indignant if, failing to properly enter his protest, his verbal protestation is not brought before the committee. The protest to which you refer should have been dealt with on the show day, but unless you were prepared to substantiate your reasons for protesting by documentary evidence it was, surely, useless to make the protest. If, however, your evidence, submitted later, has resulted in an investigation of the case and the withdrawal of an ineligible competitor, then there seems little fault to be found. That the secretary was to blame for not bringing your protest up at once we are not yet convinced, but if you properly entered the protest and was prepared with you evidence at once, then he certainly was not blameless.

NAMES OF PLANTS.

P. M., Chertsey.—Callicarpa purpurea.

F. A. F., Westgate.—1, Jasminum nudiflorum; 2, Arbutus Unedo.

W. C. T., Everton.—1, Davallia polyantha; 2, Pteris hastata; 3, Todea superba.

T. T. S., Warwick.—1, Begonia fuchsioides, 2, B. Socotrana; 3, Calceolaria Burbidgei; 4, Veronica Andersoni var.

K. F. B., Ipswich.—1, Sedum Sieboldi; 2, S. S. variegatum; 3, Oncidium varicosum Rogersi; 4, Strobilanthes Dyerianus.

OBITUARY.

◆

MR. ARNOLD MOSS.

We regret to learn of the death, at 62 years of age, of Mr. Arnold Moss, formerly head of Messrs. Jacob Wrench and Sons, seedsmen. Mr. Moss was the soul of geniality, and many will remember his jollity at the various meetings of the Gardeners' Royal Benevolent Institution, and the Royal Gardeners' Orphan Fund, both of which charities he helped in many ways.

AN ORDER SAFE PRODUCTIVE CLAY'S LONDON FERTILIZER ECONOMICAL LASTING **FOR CLAY'S**

NATIVE GUANO

BEST and CHEAPEST MANURE for VEGETABLES, FRUITS and FLOWERS.

Price **£3 10s.** per ton in bags. Lots under 10 cwt. **4s.** per cwt. at works; or **5s.** per cwt., carriage paid to any station in England.

Extracts from 32nd annual collection of reports:—

NATIVE GUANO for POTATOES, VEGETABLES, etc.

J. HAYDON, Hampton: "Potatoes, excellent crop; none diseased. Grand for keeping away slugs." G. PERRY, Westcliffe: "Peas and onions, splendid."

NATIVE GUANO for FRUIT, ROSES, TOMATOES, etc.

A. W. BRINKHAM, Hull: "Cucumbers, tomatoes, and chrysanthemums highly satisfactory." G. ACCLETON, Carlisle: "Finest manure ever used for vines, peaches, roses, carnations, etc." W. COOPER, Shoeburyness: "Most excellent for roses."

Orders to the **NATIVE GUANO CO. (LIMITED)**, 29, New Bridge Street, London, E.C., where 32nd year's testimonials, etc., may be obtained. Agents Wanted.

NOTES OF THE WEEK.

Life Cycles.

The life cycle of an organism consists of the more or less varied forms which it assumes in the course of its career from the egg-seed or germ to egg-seed or germ again. In innumerable cases this involves such metamorphoses that no one ignorant of the connection would ever dream that the one individual could possibly be the outcome of or the prelude to the other. In the plant world with which we are familiar, the seed proper develops straight into the parental form, and the life cycle is simple; but in spore producing plants such as ferns, we have an intermediate phase, the prothallus or small green scale produced by the spore, which differs so materially from the fern proper that the connection was only discovered early in the last century. In some of the lower orders of vegetation such as the fungi, the life cycle is even more complex, the spore producing ramifying and spreading growths termed mycelia, which again may produce spores of varying kinds according to the environment or the season, the original type of spore only subsequently appearing to complete the cycle. In some cases the life cycle of fungi may involve even a change of host, that is the plant upon which it lives; thus the Wheat Smut passes one phase of its existence in a different form on the Barberry, upon which it produces spores which attack the Wheat, and then yields different spores which again attack the Barberry, and so on alternately. In the animal world the transformations are even more extraordinary. That terrible disease the Sheeprot, which attacks sheep and forms large parasitic bodies on the internal organs, passes one phase of its existence within the body of a water snail, and these snails being swallowed by the sheep when drinking or browsing on the wet grass in the vicinity of the water, convey the reproductive germs of the pests into the intestines, and the comparatively colossal "fluke" is the result. The life history of the pest being discovered by microscopic study, the confinement of sheep to drier ground was found to involve absolute immunity from the disease, this constituting one of the many cases where the scientist has established the value of apparently abstruse and unprofitable poking and prying into Nature's secrets. The intermediate changes which occur in the life cycles of most insects are wonderful. The familiar examples of the Butterfly and Moth, where the egg produces a caterpillar which subsequently envelops itself in a chrysalis whence emerges the egg-laying generation, is a type of innumerable others. No fly of any description emerges as such from the egg; in every case there is an intermediate stage consisting of a creature of apparently quite another kind, and actually quite different in its habits. The Dragon fly, and Mosquito, which, as such, pass their flying existence in the air, are practically born in the water where they pass the intermediate stage as aquatic insects, and the Great Water-beetle, Dytiscus, forms a sort of intermediate link, by inhabiting the water in both larval and flying forms, while gifted with wings and the power to leave the water and take long aerial flights to find fresh pools in which to deposit its eggs. The Medusa or Jelly-fish which in the summer time we may find floating in the sea, sometimes in large numbers, and with huge discs and suspended tantacles, is even more wonderful in its genesis and career than any we have cited. It commences life as a minute, actively swimming organism born of a microscopic egg; this, after a period of activity anchors itself to a rock, and this done proceeds to grow into a series of cups one within the other, which eventually separate, each one being then a small Medusa which by simple growth becomes a large one. In this case each original germ produces not one individual but many, so that in this respect it differs materially from the other cases. More marvellous, however, than even this, is the fact which is demonstrated as such by evolutionary study, that the life cycle of even man himself involves a gradation through all the stages of existence which preceded his culmination as a human being, and this is the case with all animals, the embryo passing through all the preceding forms of life, these being metamorphosed and developed step by step until birth brings to light the type finally reached.

MR. HERBERT E. MOLYNEUX,
Hon. Treasurer, National Rose Society.

Mr. Herbert E. Molyneux, whose portrait we present this week, is hon. treasurer of the National Rose Society, and it is through his connection with this society that he has become famous. He is a young man, alert, and energetic; in no sense is he a figure-head treasurer. His keen business instincts coupled with an ardent love for our national flower make him unusually capable of taking charge of the financial side of the society's work, and when we remember that the income of the society in 1906 amounted to £2,024 18s. 8d., and in 1907 to £2,244 7s. 3d., it is at once evident that the office he holds is no sinecure. Mr. Molyneux is also a very capable cultivator of roses in his pretty garden at Brantwood, Riddlesdown Road, Purley, Surrey, where he not only grows exhibition roses, but has a collection of species and varieties of which he is justly proud. In addition to financial and cultural ability, Mr. Molyneux possesses the "pen of a ready writer," and it is a source of regret that his close attention to finance and flowers so severely limits his opportunities of contributing information for the welfare of his fellow rosarians.

Visitors to Kew During 1907.—The number of persons who visited the Royal Botanic Gardens during the year 1907 was 2,962,714. These figures represent an increase of 623,222 visitors over the year 1906, when the numbers were 2,339,492, and up to that time had established a record. The total number on Sundays was, we gather from the "Kew Bulletin," 1,268,501, and on weekdays 1,694,213. The corresponding numbers for 1906 were 867,148 and 1,472,344 respectively. The maximum attendance on any one day was 92,277 on August 5, over 20,000 less than on the corresponding day in 1906, when the attendance was a record one for a single day. The smallest number on any one day was 168 on April 26. The detailed monthly returns are: January, 39,685; February, 46,845; March, 219,498; April, 186,092; May, 406,867; June, 347,709; July, 473,309; August, 553,814; September, 485,201; October, 115,735; November, 49,154; December, 38,805; total, 2,962,714.

Colour Photography is a subject of the greatest interest, and its development is a matter of the greatest importance. When plants and flowers can be photographed in their natural colours at a moderate cost the seedsman's and nurseryman's traveller will have no need to graphically describe the special plant, flower, or fruit he wishes to push among his clientele; all he will need to do will be to show the photograph and state whether the subject is hardy, half-hardy, or very tender. The orchid specialist, whose plants vary in price according to their rarity, or the form and colouration of the flowers, will find in colour photography a splendid means of convincing prospective customers of the beauty and rarity of any odontoglossum, cypripedium, or lelio-cattleya he may have raised or acquired. There is no question as to the usefulness of colour photography, therefore we are glad to be able to announce that on January 28 Mr. Waltham will lecture at the Royal Horticultural Hall on "Self-coloured Photographs of Alpine Flora." The lecture commences at three o'clock.

A Yellow Pæony (Pæonia Mlokosewitschi) is a prominent plant among the several figures in the current issue of the "Botanical Magazine." It comes from the Caucasus, is a thoroughly hardy perennial, and the best of the few yellow-flowered kinds. Philodendron corsinianum, a climbing aroid, raised on the Continent, and one that produces large red spathes; Viburnum utile, a shrubby, white-flowered member of the Laurustinus group, from China; Herbertia amatorum, a pretty iridaceous plant from South America, with vivid violet-blue flowers; and Pseudolarix Fortunei, a beautiful golden larch, first discovered by Fortune, are other subjects figured and described in the same issue.

Early Daffodils have been rather expensive lately owing to the damage done to the flowers by frost, in the Channel Islands and on the Riviera. Flowers from Scilly and Cornwall realised high prices, but rates are now lower and steadier, as supplies are increasing.

Fire at Mr. Robson's Nursery.—We regret to learn that early in the new year a serious fire broke out at Mr. John Robson's nurseries, at Hale Road, Hale, doing considerable damage to the potting and other sheds, but, fortunately it was stopped before the houses were reached. A chapter of accidents followed the discovery of the outbreak, commencing with the collapse of the bicycle ridden by the watchman who went to summon the fire brigade. We are glad to learn the damage to the nurseries did not materially interfere with the fulfilment of orders.

Branches of the B.G.A.—The Executive Council of the British Gardeners' Association wish it to be widely known that they are prepared to support efforts to form branches in any part of the United Kingdom. They will, on application, arrange to send a delegate to address such meeting, provide handbills for distribution, and pay the initial expenses for hire of room. In the case of the establishment of a branch with a properly constituted committee and secretary, the Council are prepared to assist the branch with the necessary stationery and literature. The Executive Council also suggest that at least four meetings be held by each branch during the year, and, if possible, papers of general gardening interest should be read in addition to the conduct of the general business of the branch. The secretary of each branch is also invited to send up reports embracing any item of gardening interest, in addition to the reports of business done. A branch of the B.G.A. may be formed wherever a mutual improvement society (composed of professional gardeners) exists.

The "Sweet Pea Annual" for 1908, is an excellent production, and its editors, Messrs. C. H. Curtis and H. J. Wright, and also the society whose official publication it is, are to be congratulated upon its "live," useful, and interesting contents, and its appearance. It is stoutly bound in red cloth boards, with white lettering, and we are glad to find the back cover has not been defaced by advertisements. At present we can only briefly draw attention to the principal contents, which include: The Sweet Pea Audit of 1907; The Proeedings of the Floral Committee; A Complete List of Sweet Pea Names, prepared by Miss Jessie Cuthbertson; Sweet Pea Enthusiasts, by Mr. Hugh Aldersey; An Open Letter, by Mr. W. Atlee Burpee; More Historical Notes, by Mr. S. B. Dicks; Wire Netting for Sweet Peas, by Mr. G. W. Leak; Adherence to Principles, by Mr. G Gordon, V.M.H.; Sweet Peas in Devonshire, by Mr. R. Bathhurst; Germination of Sweet Peas, by Mr. Charles Foster; Breakers Ahead, by Mr. Walter P. Wright; and Sweet Peas in the Antipodes, by Mr. H. Fox. There are some limericks, wise, clever, and otherwise, and there are numerous illustrations of the society's trials and outings, of sweet peas in various places, and portraits of the president, Mr. W. Cuthbertson, J.P.; the chairman, Mr. E. J. Edwards; of Mr. J. S. Eckford, and of the medallists and the contributors. The "Annual," which has been copyrighted this year, should be the means of adding very materially to the membership of the National Sweet Pea Society.

Brassica Hybrids.—Mr. F. Chittenden informs us that Mr. A. W. Sutton, V.M.H., F.L.S., will read a paper on "Brassica Hybrids" at the next meeting of the Royal Horticultural Society's Scientific Committee, January 28, at four p.m., in the lecture room at Vincent Square, and will illustrate his lecture by lantern slides.

Horsham Gardens.—As previously announced, we shall describe and illustrate in the "Gardeners' Magazine" for February 8 and 15 some of the more noteworthy of the many interesting gardens in the Horsham district. Among the gardens that will be described and illustrated are those of Leonardslee, Denne Park, Warnham Court, South Lodge, Holbrook Park, Wimblehurst, and Warnham Lodge.

R.H.S. Guild.—With the view of keeping past and present students and employees in the gardens of the Royal Horticultural Society in touch with one another and with the work of the society, it has been decided to form a R.H.S. Guild. A half-yearly magazine will be issued, comprising articles and letters contributed by members, notes on the work of the society in the gardens at Wisley, exhibitions, etc., general notes of horticultural interest, and a list of members with their addresses. An annual dinner will probably be arranged for on the first day of Holland Park Show. The fee for membership is fixed provisionally at 5s. a year. Will old Chiswickites and Wisleyites please communicate with the hon. secretary, Mr. R. J. Wallis, R.H.S. Gardens, Wisley, Ripley, Surrey.

British Fruit Culture. It has been estimated that during the past ten years 12,000 acres of small fruits and 25,000 acres of orchards have been added to the area under fruit culture in Great Britain, bringing up the total area to 308,859 acres.

Improvements at the Marble Arch.—The Marble Arch that stands at the head of Park Lane and Hyde Park is well-known to every Londoner and every visitor to the Metropolis. It was originally erected as a gateway to Buckingham Palace at a cost of £80,000, and was intended to carry an equestrian statue of George IV. It was erected on its present site in 1851. A proposal is now before the London County Council to take a small portion of the Park behind the arch and convert this into a broad roadway that would render the Marble Arch much more effective and imposing, and also provide ample accommodation for the increasing traffic at this spot. It is expected that Mr. F. W. Speight's plans will be adopted. and already the City of Westminster and the boroughs of Paddington and St. Marylebone have voted £2,112 towards the cost of the improvements, and the City of Westminster has agreed to maintain the increased roadway. The "place" so created will be separated from the Park by an architectural screen. The cost is estimated at £25,000, and if the plan is carried out a fine finish will be provided to a grand processional road commencing at Trafalgar Square and passing the Victoria Memorial, along Constitution Hill and through Hyde Park.

The Midland Carnation and Picotee Society's next annual show has been provisionally arranged for August 6 and 7, at the Botanical Gardens, Edgbaston, Birmingham.

The Chilian Lichens. Almost everyone who has had to deal with importations of South American plants will know that lichens are particularly abundant in some parts of that huge area. In Chili the lichens are particularly abundant and luxuriant, as was made evident on Saturday last when Mr. R. Morton Middleton gave a demonstration on the Chilian Flora in the botanical department of the Natural History Museum. The specimens were chiefly from the Pacific Slope, and among the most notable were the big masses of various species of Usnea and the red-capsuled Physica flavicans.

Forcing Rhubarb. — We were under the impression it was a matter of common knowledge that rhubarb could be readily forced during the winter months, but it would appear that this is not the case. In a journal of good standing we read under the heading of a "New Gardening Industry" that, "As the result of tests made throughout two seasons, a well-known experimenter has proved conclusively that early rhubarb, of profitable commercial value, can be raised in quantity without considering the question of light and air. All that is needed is manure, and when that is obtainable, then winter rhubarb can be grown to perfection in the vicinity of towns." It would be difficult to say when the forcing of rhubarb with fermenting materials was first practised, but, judging from two contributions to the third volume of the "Horticultural Transactions," published in 1818, or ninety years ago, it was not generally known at the beginning of last century. The first of these contributions was by Mr. Daniel Judd a gardener at Edmonton, who states he had found the hybrid rhubarb so far superior to the type that he had "expelled" the latter from the garden under his charge. The hybrid must have been strong in growth, as the leaves are said to have extended upwards of five feet on each side of the row. In making his first attempt Mr. Judd turned common garden pots over the crowns, and presumably manure also: but as they failed to give the stalks room enough, he, in the second season used pots specially made for the purpose and without holes. These were not satisfactory, and in the third season he erected a light framework of wood over the row, and this was covered with a layer eighteen inches in thickness of stable manure. At the same meeting a paper contributed by Mr. Thomas Andrew Knight was read, and in this was described a method of forcing rhubarb in pots. The roots were lifted and put in large pots, and covered with inverted pots of the same size. The roots were then placed in a dark position in a vinery and copiously supplied with water, and are said to have produced three crops.

Slow Trains Cause Damage to Gardens.—The connection between slow trains and damage to gardens may seem rather remote. Suburban Paris has lately been provoked beyond endurance by the slowness of the train service, and one evening last week an outward-bound train crawled slowly towards its destination and finally stopped short. The passengers then showed their anger by smashing all the readily breakable parts of the carriages, pelting the railway officials, and finally by spoiling the gardens so carefully cultivated along the railway side by the employees. Righteous indignation is all very well, but those who give expression to it in this way, and vent their spite on the gardens of unoffending people, should be made to pay liberal damages.

Hexham Gardeners' Society.—This is a young society, run on mutual improvement lines; its long list of officers shows the strong local support given, and its rules are clear and few. A meeting is held early in each month at which a horticultural subject is discussed. Two nights each week the reading-room is open to members, and here the current horticultural periodicals are provided, and a small horticultural library is in course of formation. There are also competitions at the monthly meetings and the prizes are books, not money.

SUMMER FLOWERS.

At this season of the year, when the days are perceptibly lengthening, and when preparations for the summertime display in the garden are already being commenced, we look forward hopefully to the time when our garden will be bathed in sunshine, fragrant as a lily, and beautiful as a rose. It is now that pictures of last year's garden scenes appeal to us, and from them we learn what to avoid and what to introduce, what to repress and what to encourage, so that the living pictures of the present year shall be still more beautiful. It frequently happens that a nurseryman is so busy trading and caring for other folks' gardens that he neglects his own, but there are many cases where this rule does not obtain. The late Mr. Benjamin R. Cant, the famous old rosarian, was as proud of his own garden around his house as he was of his acres of roses growing beyond it. His garden has been cared for by his sons, who now so ably carry on the rose-growing business at Colchester, and the picture herewith shows how delightfully herbaceous plants are grown in the old home garden. One almost smells the fragrance of the lilies and the roses exhaled from this old garden corner, and now, as in the summer days, we admire the charm and beauty of the big hedge of Dundee Rambler rose, that is at once a line of division, a means of protection, and a thing of beauty. Such a hedge is worth copying, for the variety is wonderfully hardy, evergreen, and it flowers with the utmost freedom.

SUMMER FLOWERS.
A corner in the Home Garden at Messrs. B. R. Cant and Sons' Nurseries, Colchester.

NEW HARDY TREES AND SHRUBS.

For many seasons past it has been my privilege, through the courtesy of the editor of the Gardeners' Magazine, to give a few notes at the beginning of the new year on the different hardy trees and shrubs that have been awarded either First Class Certificates or Awards of Merit during the twelve months preceding. The past year showed a great advance on 1906, for in this last-named year no First Class Certificate was given, and only nine Awards of Merit, whereas in 1907 the number was three First Class Certificates and 15 Awards of Merit.

Perhaps the most notable feature connected with these trees is that the three First Class Certificates were all given to kinds whose introduction resulted from Mr. E. H. Wilson's travels in China. There is a widespread idea that these awards are given only to new plants, but that such is not the case may be seen by the following list of those honoured in 1907.

Several of the most interesting of these have been already figured in the Gardeners' Magazine, viz., Rhododendron Duke of Cornwall, in the issue for March 23; Rhododendron Kewense, March 30; Hydrangea arborescens grandiflora, May 18; Viburnum rhytidophyllum, May 18; Vitis inconstans Lowi, October 5; and Vitis leeoides, November 9. The list of certificated subjects is given in the order in which they were shown.

Magnolia Soulangeana nigra.—A particularly rich coloured form of Magnolia Soulangeana, itself a hybrid between the Yulan (M. conspicua) and M. obovata, also known as M. purpurea. This fine variety nigra was, when shown, looked upon by many as a novelty, but I made its acquaintance nearly a quarter of a century ago. It was believed to have been brought from Japan by the late Mr. John Gould Veitch. Award of Merit, March 19.

Rhododendron Duke of Cornwall.—A gorgeously coloured really grand variety obtained by the intercrossing of the two Himalayan species—R. arboreum and R. barbatum. These Indian species and their hybrids thrive particularly well in the West of England, especially in Cornwall. Award of Merit, March 19. The specimens were sent by Mr. R. Gill, Tremough, so well known as a successful cultivator of these beautiful shrubs.

Rhododendron Kewense.—A delightful hybrid raised at Kew between R. Griffithianum, far better known as R. Aucklandi, and R. Hookeri. The flowers are large, borne in loose heads, and in colour usually some shade of pink, but some are of a deeper hue and others almost white. Rhododendron Kewense was raised at Kew as long ago as 1875, but it did not flower till 1888. Numerous individuals of this section planted out in the rhododendron dell at Kew form annually a striking feature. Award of Merit, March 19.

Rhododendron intricatum.—Under the name of R. nigro-punctatum, this charming little species was given a first-class certificate on April 2. It is a native of Western China, and has proved to be quite hardy at Coombe Wood. In a state of nature it was found by Mr. Wilson to attain a height of 1ft. to 3ft., but under cultivation it will flower when but a few inches high. The flowers, borne usually in clusters of five, are individually about three-quarters of an inch in diameter, and in colour deep lilac. For the rockery or alpine garden, and for associating with the smaller growing ericaceæ this rhododendron will doubtless prove to be a decided acquisition.

Pyrus (cydonia) japonica Simoni.—By no means a novelty, but a particularly fine, bright, rich-coloured form of the well-known Pyrus japonica. Award of Merit, April 30.

Hydrangea arborescens grandiflora.—A distinct and very fine variety of the North American Hydrangea arborescens. The typical form of this species has the large sterile flowers, which form the showy part of the inflorescence, limited to a scattered few around the outside of the cluster, but in this variety they make up the entire head in the same way as the common hydrangea. The colour is creamy white. An Award of Merit was given this hydrangea on May 14, and many anticipate a great future for it.

Cytisus Firefly.—A seedling form of Cytisus Andreanus, which in richness of colouring is a considerable improvement on the type. Award of Merit, May 28.

Actinidia chinensis.—A recent introduction from Central China, this forms a vigorous growing climbing plant furnished with large heart-shaped leaves, dark green on the upper surface, and densely tomentose beneath. The leaves are when young thickly covered with bright red hairs. For pillars or pergolas this will prove a good companion to the many large-leaved vines that have been sent out within the last few years. Award of Merit, May 28.

Rhododendron (Azalea) Madame Anthony Koster.—A very fine form of Azalea sinensis or mollis, with large well-shaped flowers, in colour yellow, with a pleasing suffusion of pink. Like other varieties from the same source, it is no doubt destined to become popular. Award of Merit, May 28.

Lonicera Maacki.—This belongs to the non-climbing or shrubby members of the honeysuckle family, and towards the end of May or in June it forms a very handsome object in the open ground. It forms a freely branched bush, whose slender arching shoots are clothed with ovate acuminate leaves a couple of inches or so in length, and closely studded with clusters of creamy-white flowers. A native of Manchuria this was introduced into cultivation by way of the St. Petersburg Botanic Garden about 25 years ago. Despite its desirable features, it is even now but little known. Award of Merit, June 11.

Syringa Josikæa eximea. — A very superior variety of the Hungarian lilac, which bears large pyramidal shaped panicles of rich reddish rose-coloured flowers. They are pleasingly fragrant, and their value is enhanced by the fact that they are borne after all the forms of the common lilac are past. Award of Merit, June 11.

Hedera dentata variegata.—A form of the well-known H. dentata, which differs from the type in the foliage, being freely variegated with white, which in the young leaves has a creamy tinge. Award of Merit at Holland House, July 9.

Rubus cambusarum.—A very distinct bramble from Central China, with trailing branches from 10ft. to 12ft. long, having usually three leaflets, but occasionally five. These leaflets are lance-shaped and smooth on the upper surface, but the lower side is covered with a dense dun-coloured tomentum, as are also the young shoots. The flowers are in terminal racemes, and give place to black edible fruits. Botanical Certificate, August 20.

Viburnum rhytidophyllum. — A bold growing evergreen shrub, whose striking foliage will no doubt ensure it a place in many gardens. The leaves, broadly lanceolate in shape, are from 8 to 9in. in length, by 2 to 2½in. broad, the upper surface being dark green and very much channelled, while the under side is covered with a dun-coloured woolly tomentum. The flowers, borne in dense corymbs, are of a yellowish white colour, and expand in May or June. They are succeeded by berries which at first bright red become afterwards almost black. Flowering examples were exhibited at the Temple Show, and a specimen in full fruit was given a First Class Certificate on September 17.

Vitis inconstans Lowi.—This is a charming seedling form of the climbing plant so generally known as Ampelopsis Veitchi, but whose correct name botanists now tell us is Vitis inconstans. This new variety differs from the typical form in its small deeply-cut leaflets, while it is in every way a more graceful plant of a lighter character than its parent. In summer the foliage is of a beautiful metallic green, changing to a bright red in the autumn. Ampelopsis Lowi was raised by Messrs. Hugh Low and Co. at their nurseries, Bush Hill Park, Enfield, and an Award of Merit was given it on October 1.

Cotoneaster applanata.—An extremely promising species of cotoneaster, and one that when distributed is no doubt destined to become popular. As shown it formed a very graceful specimen, the branches arching outwards and drooping away from the leading central stem. The heart-shaped leaves are small, while the clusters of scarlet fruits extend for some distance along the branches. It comes from China, and was given an Award of Merit on October 1.

Vitis leeoides.—A recently introduced Chinese vine of robust habit, with very handsome foliage. The leaves consist of three or five oblong leaflets, which are glossy green above and purplish beneath. For the clothing of pergolas and similar purposes a considerable demand may be confidently anticipated for it. Award of Merit, October 1.

Berberis Wilsonæ.—A charming little barberry collected by Mr. E. H. Wilson in Western China, and named in honour of his wife. Its slender branches are thickly clothed with narrow leaves about half an inch long, and plentifully furnished with reddish spines longer than the leaves. The flowers are golden yellow, and the berries which succeed them change to a bright red when ripe. It was in this stage when a First Class Certificate was awarded it on October 15. Mr. Wilson states that in its native habitat the leaves are in autumn most brilliantly coloured. There is undoubtedly a great future before this barberry, which has proved hardy at Coombe Wood.

Juniperus chinensis nana aurea.—This, the only conifer recognised during 1907, is a form of the variable Chinese juniper. It is of a dwarf cushion-like habit and of a pretty golden hue. Award of Merit, November 26.

W. T.

Chrysanthemum, Mrs. J. Hygate.—Referring to Mr. Molyneux's remarks (pages 932 and 933, 1907) on Chrysanthemum Mrs. J. Hygate, are we to understand that rather than show this variety as a giant, though perfect, incurved from a late bud, we should place a seven or eight-inch flower of it in the front row of a board of Japanese varieties that include in the back row a 16-inch bloom of F. S. Vallis? Many, like myself, would also be glad to learn how these relative measurements—eight inches and sixteen inches diameter—are obtained.—R. Barnes, Malvern.

THE WILD GARDEN—I.

In wild gardening the aim should be to copy Nature in her most attractive guise. Some subscribe to the fallacy that the term "wild" implies disorder, but there can be no greater misapprehension, for Nature, however vigorous she may be, is never disorderly. Even in tropic forests, where growth is rampant, each huge leaf and giant trailer serves but to complete the picture of superabundant vitality, without conveying any suggestion of confusion. There should be no desire or attempt to remodel Nature, but merely to supplement her scheme by the introduction of native or hardy exotic plants whose presence would add to the attractiveness of the view.

In the herbaceous border and the rock garden it is impossible to predict with any certainty that, by following some particular treatment, success will be inevitably assured, and in the wild garden this holds good to an even greater degree. There are so many differences of climate, aspect, and soil to be considered that no general rule can be laid down. What succeeds in Yorkshire may fail in Devonshire, and vice versa. A plant that is a weed in moist Western Scotland may not improbably refuse to exist in Surrey sand. Though much may be learnt from others, experience is the only safe teacher of the likes and dislikes of plants in any particular locality.

The possibilities of the wild garden are very varied. Fields, open glades between copses, woods, boggy ground, and the surroundings of water are all available for the naturalisation of effective plants, while steep rocky slopes will often afford as fitting a home for alpines as the most skilfully constructed rock garden. The list of subjects suitable for planting in the wild garden is a very lengthy one, for not only are the natives of the temperate regions of the globe available for our purpose, but the mountain heights of the tropics provide many a desirable plant that will not resent its change of latitude. In the very wideness of the selection, however, danger lurks, since the planter may be tempted to experiment with so varied a collection that all similitude to Nature's grouping will be irretrievably lost—and Nature must be the teacher.

The dotting system is atrocious in the herbaceous border, but in the wild garden, where natural effect should be the guiding note, it is infinitely worse. It is far better to err on the side of too few genera and varieties than too many. Nature spreads her flowers in wide drifts of one species, mile-long colonies of gladiolus on the South African veldt, flower-enamelled Alpine meadows, where sheets of Gentiana verna glow in their intense blue under the mountain sunshine, or Eritrichium nanum paints the rocky spaces with its tenderer tint, a flower that, singly, is insignificant, forms a feature in the landscape when growing in massed thousands.

One of the chief merits of the wild garden is that it requires no continual striving to keep it tidy, such as is indispensable with the beds and borders surrounding the house. The herbaceous perennials wither and die where they stand, just as do the native inhabitants of the ground. In woods of deciduous trees the falling leaves rest thickly on the earth, rotting and enriching it. The wind that blows the russet leaves hither and thither about the trim garden plots has no effect in the wood, where the countless stalwart trunks and innumerable interlacing branches form an effectual barrier to its violence. In the spring the tall browned stems of lilies, that have never known a stake, may be seen still standing intact, affording evidence that they have escaped the furious onslaughts of the wind endured by their sisters in the open border. Such sights lead to the recognition of how greatly plants are benefited by the encompassing shield of the wood.

Again, the wood does not limit its beneficence to the bitter winter season alone, but, in the arid summer days, when from the parched earth beyond its limits the heat rises in tremulous exhalations, it affords a cool retreat for many a pretty plant. The cyclamens and hepaticas love a gentle shade, and are never as happy in the sunny border as within the confines of the wood.

Some care should be exercised in the provision of plants for the wild garden. Bulbs are, naturally, procured in a dry state, and planted. Herbaceous plants should be well prepared before removal to their destined positions, for it is of the utmost importance that they should be in as vigorous a state of health as possible at the time of their planting. For this reason it is unwise to purchase a number of subjects from a nursery and plant out at once where they are intended to remain. A far better plan is to place them, upon their reception, in a rich border in the kitchen garden, where, in a season or two, they will gain immensely in vigour and size, and may then be transferred, with little risk, to their permanent quarters. The best plan is, however, to grow the plants from seed, cuttings, or divisions, in a reserve garden, and plant them out when they are large enough.

The roots of all strong-growing herbage should be removed from the ground for a distance of three feet around the proposed sites of the plants, and the soil well dug up and plentifully manured, for it is of the greatest importance in the wild garden that the plants should have a good start. Those who are of opinion that all that is necessary is to dig a hole in the ground, put the plant in, and leave it, will inevitably lose much, for the established occupants of the ground will probably choke the newcomers before they have gained a secure roothold, whereas, if the spot is well manured and cleared of competing vegetation, they will have had sufficient time to become thoroughly established before this again intrudes upon their precincts.

S. W. FITZHERBERT.

CHRISTMAS ROSES AS CUT FLOWERS.

There are two complaints generally brought against the Christmas rose as a cut flower, and both are the result of knowing so little about the plant and its flowers. The first is that the flowers have such short stems that it is impossible to arrange them nicely—I have even seen it suggested that the only way of using them satisfactorily is to float them in saucers of water! The second is that the flowers flag in water, and never do themselves or their arranger justice.

A VASE OF CHRISTMAS ROSES.

In some cases both these complaints are justified, but the grower of the plants and arranger of the flowers can then neither be absolved from blame. The old form of Christmas rose, Helleborus niger, does produce short-stalked flowers, and will reduce the stalks to almost vanishing point in poor ground. But what is known as the Bath Christmas rose, Helleborus niger maximus, will give flowers in plenty on six-inch stems, and I have had them over ten inches in length.

The charge of hellebores flagging after cutting is distinctly founded on fact, as anyone who has handled the long-stemmed, spring-flowering species and varieties can testify. But this flagging is remedied just as easily as the shortness of stem, and withal just as simply. Before putting a hellebore of any sort in water cut off the end of its stem afresh, and slit the stem up lengthwise for an inch or two, and no flagging will follow.

When it is remembered that Christmas roses will retain their freshness as cut flowers for from two to three weeks in a cool room, anything which makes for their wider use cannot be too generally known. I use them in many ways, and find them invaluable.

E. J. K.

DECORATIVE WINTER-FLOWERING PLANTS.

The provision of a continuous supply of flowers under glass, either for cutting or otherwise, often taxes the grower in a private place, and at no season of the year is the difficulty greater than in the interim between the flush of chrysanthemums and the time when forced bulbs are easily procurable. Even then these leave something to be desired, for they are quite unsuited for use in tall vases, and one is often hard put to it for material to fill such vases in the free and graceful style which is a feature of present-day floral decorative work.

Winter-flowering carnations have of late years filled a gap in this respect, but even these have their limitations, and one cannot keep the supply going without ample means in the way of house room, as the flowers open but slowly under our winter skies, and it takes many dozens of the blooms to make a good display on the dining table when the latter is laid for a score or more covers, and to keep this up day after day requires a huge supply, even though the individual flowers last well.

Poinsettias (Euphorbia pulcherrima) are excellent decorative plants, either for cutting or for grouping, and a good batch of these should always be grown where a winter display is demanded. Used in water as cut they very soon flag, but if a small portion of the cut stems are immersed in almost boiling water directly they are severed, the milky juices are sealed up and the heads remain fresh and good for many days. E. jacquiniæflora is also excellent for small decorative effects, but is only desirable where it can be really well grown in bulk, under which conditions it is one of the brightest and showiest plants that can be grown.

The Arum Lily (Richardia æthiopica) is also an excellent winter-flowering plant of larger growth, and a big batch of this should always be grown, for it can be had in flower by Christmas without trouble, and, given an intermediate temperature, plenty of light, and good feeding, the same batch of plants will go on flowering for several months, and though the display of spathes may not be great at any one time the aggregate return is excellent.

Anthuriums of the Scherzerianum section are excellent plants for flowering in the early part of the year. As generally seen dotted about in the stove they have not much to recommend them, neither are they valuable for cutting if only a few spathes can be cut at one time and used in conjunction with other flowers, but where they are well grown in quantity they give a display not easily forgotten, and when the spathes can be cut by the dozen or score they lend themselves to decorative work with great effect, if used in mass with no other assistance than suitable greenery. At present (mid-January) we could cut quantities of spathes measuring seven inches by three and a half inches, on stems three feet and more long, and the display of brilliant scarlet these give can be imagined. They last for a fortnight in a cut state. I know of few more satisfactory plants, as the leafage is always attractive. A passing word as to culture, or rather management, is that they are usually grown in a temperature too high to suit them, as may be imagined when I say that we are quite satisfied with a minimum temperature of 55 degrees in cold weather, and at no period are they allowed a high stove temperature except by sun heat, and from this they are heavily shaded.

A group of bulbous plants that has given great satisfaction as winter-flowering plants is the amaryllis or hippeastrums. As generally seen these are essentially spring flowering, and at their best in April, but an educative system of early growth will be readily responded to by early flowers. We grow these rather largely here, and since November have not been without a number of spikes in flower. By the middle of February at least 90 per cent. of the bulbs will have flowered, and this earliness does not mean poor flowers or weak stems. Many of the former have been eight inches to nine inches across, and borne on stems three feet to four feet high. Many bulbs have carried two spikes, and from some seven-inch pots containing more than one bulb as many as ten flowers have been produced, the strongest spikes usually bearing four flowers each.

Very little artificial heat or forcing has been given to the production of these; it is mainly the result of good feeding during the growing season, and thorough ripening of the bulbs after growth has finished, from which time they occupy shelves near the glass in fig houses and vineries, where they become firm, and in good trim for early production of spikes. Hippeastrums should certainly be more often and more largely grown for winter use. My method of treatment differs from that generally advised in that whatever potting we do is done directly after flowering, and not when the bulbs are dormant. This suits our conveniences best. The bulbs are not potted annually, but in any case a considerable portion of the old soil is removed and its place filled by a mixture of loam, leaf-mould, sand, and a little bonemeal, and this treatment appears to suit them well. If there is any falling off in condition of the bulbs,then they are shaken out and repotted in similar soil and in well-drained pots.

Hippeastrums are frequently injured by a too free use of the waterpot early in the season. One good soaking of water given after the flower spike shows, not before, is sufficient to carry the plants to the time the buds show. Frequent watering causes decayed roots, and a soft formation of the bulb that soon leads to disease.

The provision of greenery for cut flowers is not always well considered. Here our old friend the Solomon's seal is one of our most satisfactory plants for the purpose, as it gives height and a delicate greenery that makes it suitable to use in conjunction with most flowers. Home-grown crowns force readily if they are not allowed much exposure to light or a dry atmosphere until growth begins, and it may easily be had in good condition quite early in January.

Cyclamens, too, give a thoroughly good mid-winter display if the seeds are sown in August and the plants are grown on without a check. Seeds that produce plants true to colour may be purchased—none being more effective than the type known as Salmon Queen—so that a decorative scheme of colour is possible with these alone. Here, in Derbyshire, it is quite essential to secure for these a supply of rain water, as the plants will not grow if the hard water of the district is used for them.

Harking back to the chrysanthemum, I would like to suggest that more care be used in selecting varieties for use as cut flowers, and especially on the lines of their lasting properties when cut, for few species of plants vary more in their capabilities in this direction than do chrysanthemums. It is galling to find, say, a large vase of flowers set up yesterday withered to-day, and this is what often happens if care has not been taken to select the best varieties for the purpose. Unfortunately many of the best varieties for cutting are not suitable owing to want of size or some other defect. For many years I have made a special study of this matter, and new varieties are chosen with a view to cutting; for one plant will then do double or treble duty, as compared with some others. If the flowers do not "last" the variety is soon discarded. Among the large-flowered section there are many which last well and are of good colour, so that one is not confined to small-flowered varieties only.

With all the plants mentioned in these notes one has the satisfaction of knowing that they have been home grown, and that variety may be had during the depth of winter without dependence on imported bulbs, useful and important as these are, and it appears to me that much more might be done in this direction.

Of course, I have only touched the fringe of the subject, there being many other good winter decorative plants that I have not mentioned, but which may be not less worthy than those I have selected.

J. C. TALLACK.

Shipley Hall Gardens.

PRIMULA POISSONI.

Among the numerous species of Primula which have been from time to time introduced into our British gardens the very beautiful Primula Poissoni deserves to take a high place, although it must, unfortunately, not be considered absolutely hardy in every part of the United Kingdom. In many mild parts it is hardy, but in some which are not subject to the most intense frosts we experience in these islands it only stands the milder winters, and in such seasons as that of 1906-7, failed to survive. It is thus entirely unsuited for any of the colder districts, save as a plant grown under glass, and preferably in a structure from which frost is just excluded. It can, of course, be wintered in a cool house, and planted out to bloom, its flowering period being from June until September—a desirable time for such a flower to bloom, as we have not too many of the Primulaceæ in flower at the time.

In cultivation I have never seen it reach anything like the height given in works of reference, and about a foot is that which it generally attains in the open air. It has rather narrow and oblong, stem-clasping leaves, serrated at the margin, and good stems bearing several whorls of rich purple flowers, generally rather more than half-an-inch across.

It is a very striking primula in its way, and but for its suspicion of tenderness, would have made its way largely into the gardens of many. In my own experience outdoors I found it do best in a somewhat cool exposure, such as the north-east, but well sheltered from cold winds, and in a soil of peat, loam, and sand, with a plentiful supply of water in spring and during the flowering period. In pots it should have the above compost in a six-inch pot, and a plentiful supply of water, with good drainage. P. Poissoni is best raised from seeds sown as soon as ripe or in spring under glass. It is a native of Yunnan, China, and was introduced to cultivation as far back as 1889.

S. ARNOTT.

Dumfries.

The Value of Flowers imported into the United Kingdom during 1907 was £233,641, as compared with £233,841 in 1906, and £202,217 in 1905.

GEUM CHILOENSE (SYN. COCCINEUM).

The Common Avens (Geum urbanum) of our hedgerows is a near relative of the geums of our gardens. Though it is not so showy as many, yet of all the perennials of the garden I know of none which keeps in flower for a longer time than this, for it comes into bloom so early as almost to entitle it to be called a late spring flower, and if the old flowering stems are cut off occasionally it will continue to produce at least some blossoms until the late autumn. It is useful for cutting, and lasts a long time in water, though a drawback to it for this purpose is that it cannot be cut without sacrificing a good many buds.

There are one or two forms of Geum chiloense (erroneously called G. coccineum) that have single, bright orange-scarlet flowers; G. c. grandiflorum has larger flowers, and is of stouter habit, while the semi-double form of this G. c. grandiflorum plenum is a general favourite, its flowers being of a dazzling scarlet, and lasting longer in bloom than the single form, as is the case with some other flowers when doubled, notably the potentilla.

This geum will grow in any soil, and though some recommend it for well-drained and sunny situations, I have found it grow more vigorously, and produce a more constant succession of blossom when in a somewhat damp and well-manured soil in partial shade. It does not stand moving well after it gets established, the roots being deep and fibreless, and if taken up and divided it takes at least a season or two to recover its vigour and floriferousness. It can be easily raised from seed, and I have found seed saved from the double form of G. c. grandiflorum come fairly true, though not perhaps so large-flowered, or so fine in form as the original.

If seed is sown in April on a bed of prepared soil, with which has been mixed a good proportion of leaf-mould, and the seedlings are pricked out when large enough, they will make nice little plants for putting out in permanent quarters in the autumn. They will bloom the following summer, making large strong clumps for the next season. The method of flowering is not altogether pleasing to the slave of tidiness in the garden, as the flowering stems fall down and spread over a good deal of space, and it is a question of taste whether the plant should be allowed to grow perfectly free, or given a little support with two or three short sticks. I think the latter way has something to recommend it if the sticks are concealed by judicious tying up, and the natural grace of the plant is not injured thereby. It has the advantage of bringing the flowering stems together, by which a finer display of colour is produced than when they are spread over a larger area.

A large patch of plants together is much more effective than one or two isolated examples in a mixed border, and by reason of their spreading nature when in flower the interspaces are good positions for spring bulbs, especially tulips, the leaves of which will not fall over and smother the plants so much as narcissus. Some lilies, montbretias, gladioli, and other upright-growing bulbs are good in theory, but in practice it is found that the geums extract too much moisture from the soil in the summer-time for anything growing between them to have a chance of succeeding without much watering and feeding. It is just this dryness, however, which spring-flowering bulbs like in the summer.

Alger Petts.

LAVATERAS.

With the possible exception of L. trimestris, an annual plant everyone grows, there is but little interest taken in the lavateras or Tree Mallows, although they are capable of giving a splendid display practically all the summer long, out-vying hollyhocks in their own sphere of usefulness. The two best species are L. cachemiriana and L. thuringiaca, but beyond noting that L. cachemiriana is the dwarfer plant, they may be considered as one. They make sturdy bushes six feet through and eight feet high, if given a good soil, whilst in the second year there is a greater girth than height owing to a veritable thicket of growths that follow the primary one. The flowers are of typical mallow shape, coloured a pretty shade of pink, and they are as refined as they are beautiful, recalling some species of hibiscus in their airy poise on the slender foot stalks.

It is quite an easy matter to develop seedlings into specimen clumps; they require little or no cultivation to develop them normally, but where giant pyramids are required studded with large flowers in such quantities as to be literally described as countless, there must be no stint of manurial aid, not in the seedling stages, but when the main stems branch freely. Those who have not hitherto tried lavateras for the flower border will be astonished at the splendid display they can give, there is nothing coarse in flower or foliage to offend the eye, but simply an elegant bush-pyramid of pretty digitate leafage and showy pink flowers that are artistic individually and effective in quantity. They are easily reared from seeds, and if one plant happens to flower itself to death before its time it will be quite in accordance with what sometimes happens to lavateras.

G. B. Mallett.

LAURUSTINUS.

In many old gardens there are huge bushes or trees of the common Laurustinus (Viburnum Tinus), and these have been very effective during the last six weeks or more, and will continue to add some brightness to their surroundings for some time to come. Nowadays, however, the laurustinus seems to have fallen into bad odour, judging from the manner in which it is omitted from so many new plantations of shrubs. On Christmas Day I walked up through Worcester Park, in Surrey, and was much impressed by the number and beauty of the big bushes of laurustinus that brightened so many gardens in that pretty locality. A few sprays cut and placed in a small vase, or larger branches set in a large receptacle, form no mean ornament at the end or the beginning of the year, therefore, when planting is again occupying attention, it will be worth while to consider the claims of laurustinus, without in any way forgetting the claims of more modern flowering trees and shrubs.

SPRAY OF LAURUSTINUS IN VASE (VIBURNUM TINUS HIRTUM).

Two especially good varieties of V. Tinus are V. T. hirtum, represented in the accompanying illustration, and V. T. lucidum. The former has hairy undersides to the leaves, and its flowers are very long-lived. It is a good variety for pot culture, or for window boxes. V. T. lucidum is later in flowering, and it bears larger heads of white bloom, and has larger leaves than the former.

K. C.

PREPARING FOR SPRING.

With the turn of days there are usually many operations in gardening that need special attention. The glass structures may have all been washed down, and the houses made ready for forcing; potting composts may be in readiness for the plants as they require it; pans and boxes ready for seed sowing, and potatoes in the storehouse stood up ready for sprouting; but one of the most difficult tasks that falls to the lot of the gardener in some places is making out the seed orders. It has been remarked by some folks that gardeners order things indiscriminately, but if these people did but know the hours some gardeners spend in pondering the various seed catalogues that reach them, in order that their employers may have the most up-to-date varieties—and yet, at the same time, keep down the seed account to the lowest possible limit, they would withdraw these accusations, and offer an apology for having made them.

When making out a seed order for a garden of any specified size, many things ing a considerable time in making out a have to be taken into account. The requirements of some establishments are much greater than those of others, and some gardeners are able to produce far more from a specified piece of land than others can, for not only is the soil more productive in some places than it is in others, but the situation may be more favourable, and more labour employed. For these reasons it is useless to state what the seeds for a garden should cost. But it sometimes happens that after spend- list, this is submitted to the employer, who reduces it considerably, and at the same time expects his gardener to produce quite as much as those who have a free hand in ordering what they consider necessary.

CYPRIPEDIUM SULTAN.
Flowers green, white, and brown. F.C.C., R.H.S., January 14.
Major Holford, Westonbirt, Gloucester.

We will take flower seeds as an illustration, as these, in many instances, form the chief part of the order. Packets of some kinds are very small indeed, containing only a dozen seeds in each, and where from three to four hundred plants of these particular kinds are required, from ten to a dozen packets of seed are necessary to produce the requisite number, whereas the employer may consider two or three packets sufficient. When seedsmen make up packets they should state the number of seeds a packet contains at a given price, then we know what to expect.

When making out these seed orders one must therefore be guided by circumstances, and when that most unthankful task is completed, the mind is somewhat relieved. Then the seeds arrive, and in some instances we are annoyed to find that the very variety we wished to try most is omitted, and another substituted for it. This may be because the order was not sent in until the season was far advanced, or there may have been a special run on that particular variety; but it would be far more business-like if the seedsman to whom the order was given would write and say he was sold out, and ask if he should substitute something else, instead of sending varieties that one does not require.

Sowing seeds requires some knowledge, as many kinds are so small as to be almost invisible, particularly to those whose eyesight is not of the best, and, as before remarked, when there is only about a dozen of such seeds in a packet, the operation needs special care. These small seeds must be kept at a certain state of moisture, otherwise the germ, being so minute, withers before development can take place. Preparation must therefore be made in the way of shading that the sun's rays may not injure these delicate morsels.

Preparations must also be made for cuttings of various kinds. It is useless to say when certain plants are required that one forgot to put in the cuttings, or that a sufficient number were not provided. Better by far have a few extra than not enough. When the weather is unfavourable for outdoor work boxes of various sizes could be made ready for propagating, so that when the time arrives for such work there need not be any delay. Gardening, if it is to be carried out in the most approved manner, requires much forethought, and it is only by such timely preparations that one is able to cope with the many and varied duties that fall to the lot of those whose business it is to conduct a good-sized establishment. Some people I know wonder why it is necessary to have a stock of such things as packing boxes, insecticides, and various other requisites that are needed for a garden, but it must be remembered that gardens, for the most part, are in rural districts, and one cannot go next door and borrow of one's neighbour like a bad housewife, neither can one run to a shop in a few minutes and get what is required for the time being. For this reason then it is necessary to make preparations some time beforehand, and procure a stock of all those things that are needed to carry one on for at least three months at a time. Further, there is economy in procuring a stock instead of driblets. It is quite certain that half a dozen men cannot use the same tool at one time, and if this were possible they could not do the work to advantage.

Now that work is slack, such implements as mowing machines should be overhauled, and should any repairs be necessary these should be taken in hand at once that the machines may be ready for use when the lawns will need to be mown. There are many such items as preparing flower stakes, pea stakes, etc., that could be done in wet or unfavourable weather, which will be found of great advantage later on in the season, when the busy time comes round. It is of great importance to keep the work well in hand at this time of the year, so as, in a measure, to relieve the pressure later on. H. C. PRINSEP.

BEAUTIFUL GARDEN HEDGES

Hedges that are not boundary markers can be made of many beautiful flowering shrubs, some of which are seldom used for such a purpose. For example, nothing can exceed the loveliness of "syringa" hedges enclosing a rosery, or beds of roses and liliums, set either in grass or gravel. There are several excellent varieties of the "syringa," or mock orange, Philadelphus rosæflorus being one with immense semi-double blossom; P. Gordonianus coming into beauty rather late, and being especially prodigal of bloom; and P. parviflorus claiming attention as an extra rapid and tall grower. Then the exquisite Philadelphus purpureo maculatus might be represented, whose large white blooms have a mauve-rose blotch on each petal.

Hedges of mingled varieties of one shrub are usually more successful than those in which different species of shrubs are combined, yet the latter have plenty of charm and should be planted in situations where uniformity of height is not required. One might contain Philadelphus rosæflorus, Escallonia macrantha, Viburnum opulus, Cistus ladaniferus, laurustinus, Ribes sanguineum, and Symphoricarpus radicans, the snowberry tree. All could be pruned into some kind of regularity, and this hedge in a small garden would certainly serve to introduce beautiful subjects for which room could not otherwise be spared. Escallonia macrantha Ingrami is much hardier than is generally supposed; it seldom fails in the walled-round garden, except in coldest counties, thrives in a heavy soil, and grows remarkably thick and high; the bottom density can be annually increased by layering some of the lowest shoots. As a dividing line between flowers and vegetables, or to enclose the environs of a summerhouse, it is one of the most attractive of all shrubs.

Japanese honeysuckle makes a good hedge in time, if given some faggot supports in its youth, so too does the common white jasmine; this last I have seen delightfully used with the white Scotch heavily-spined rose as a kind of undergrowth; indeed, Rosa spinosissima shows at its best when thus employed, but is equally at home with the tall Penzance briar roses or common sweet briar. A well-grown hedge of sweet briar is, by the bye, one of the most fortunate possessions of any garden, for it can be ruthlessly cut back and down to keep it trim and green, and serves as an ideal support for any of the light-growing summer climbers, convolvuluses, sweet peas, canary creeper, Lophospernum scandens, Eccremocarpus scaber; even the profusely-leaved cobæa will not harm it. Gardeners who wish to treat such a hedge in a unique fashion should plant out some Plumbago capensis of good height against it next summer; supposing the hedge to have one side facing south; the gray-blue blossom will make a fine show.

In warm sheltered places hedges of Berberis Darwini succeed admirably; if there are cold winds feared from one quarter let a double hedge be planted consisting of a row of dark holly, or euonymus, on the cold, and the berberis upon the warm side. When a privet or laurel hedge has become bare at the base, as is often found to be the case in neglected gardens, the effect can be improved most rapidly by planting along it a line of gorse; this will flourish and flower, and in time grow up even inside the evergreen hedge, bursting through it here and there and everywhere with masses of cheerful golden blossom. I have improved old ill-kept laurel hedges, by the bye, with the common bracken fern; the fine fronds look charming as they thrust themselves through the sides, and up above the evergreen foliage.

For a thin hedge Symphoricarpus racemosus is admirable; the spring foliage is of a heart-cheering pale gay green, the pink and white florescence makes a show, although the individual blossoms are small, so lavishly is it spread over the branches; later in the year, when the stems are so heavily laden with white round fruits that they nearly lie upon the ground, the beauty is yet greater.

A rather tall hedge of well-trained laburnum makes an original feature in a garden, for this tree consents to bloom well even when it has been greatly cut back. For exposed seaside gardens nothing can be lovelier or more serviceable than Tamarix gallica, which easily reaches a height of six feet, and will ultimately attain ten, yielding a harvest of pinkish blossom-clad branches, as well as possessing elegant freshly-green, feathery foliage.

M. H.

ODONTOGLOSSUM BINGELIANUM.
Flowers yellowish-green, red-brown, and white. F.C.C., R.H.S., January 14. Baron Schroder, The Dell, Egham.

LAGASCA'S ROSE CAMPION.

Among the alpine flowers which have proved a frequent disappointment to the ardent cultivator with less knowledge than enthusiasm, we may well include the pretty Rose Campion called Lychnis Lagascæ. One has found many keen growers of these flowers who have purchased plants or have raised them from seeds, but who have had to admit their failure to retain Lagasca's Rose Campion for any length of time in their gardens. This is not due to any true want of hardiness inherent to this pretty little native of the Pyrenees, but simply because they did not know its two main enemies, and did not consequently guard against them.

These enemies are winter's damp and slugs or snails, and of these the more destructive are wintery damp and heavy rains at the same season. Slugs and snails do not abound in every garden, although they are generally more prevalent in places where the other enemy is most potent—in gardens in wet districts. Thus those whose lot is cast in dry neighbourhoods have a much better opportunity of succeeding with this lychnis than those in wetter parts, and many of these can cultivate it successfully in a dry and sunny chink in the rock garden. Yet even in these it sometimes fails, and the wall garden will generally be found the most satisfactory home for the plant, which, when of considerable size, as we may see it in a few gardens, is charming in the extreme.

A sunny wall garden, with the plant growing between the interstices, and, if possible, into a small body of earth behind, is an excellent place for this flower; and in wet localities it is not difficult to have the stones above arranged in such a way that a small piece of glass or a thin flat stone or piece of slate can be inserted to throw the rainfall in winter off the plant. In such a position the lychnis will increase in size and beauty for many years; whereas on the level or even on a sloping rockery it would die off. On the other hand, it is needful here to watch carefully against slugs, as these pests cannot be warded off by such means as are commonly employed, and naught but persistent and almost nightly search for, and destruction of, these enemies in places where they abound will suffice to save the plants from being cropped to the root.

But Lagasca's Rose Campion well deserves this trouble where time will permit of it, as a good plant covered with rose-coloured flowers, with their white centres, and showing but few of its glaucous leaves, is very beautiful indeed. It likes a gritty soil, and ought to be firmly planted, care being taken when placing it between stones that no space is left unfilled with the soil. Young plants are the best to use in establishing them on a wall, and seedlings raised under glass from seeds sown in February and March may be planted out in May for subsequent bloom. Seeds can be purchased from seedsmen who make a speciality of such plants.

S. ARNOTT.

Forthcoming Books.—The Oxford University Press has in preparation "Types of Floral Mechanism; a selection of Diagrams and Descriptions of Common Flowers," by Professor A. H. Church. Messrs. Macmillan and Co. will shortly publish "The Origin of a Land Flora," by Professor F. O. Bower; and Messrs. Cassell and Co. announce for publication "Gardening for Women," by the Hon. Frances Wolseley, who has founded a school for lady gardeners at Glynde, Sussex.

CARNATION NOTES.

Perhaps the most notable feature of the Winter-flowering Carnation Society was the conspicuous success of the Guernsey growers. This, I take it, is but another proof of the beneficial influence of the sea-air. The clear, sweet, yet salt-laden breezes seem to have the power of imparting a robustness and vigour which so many growers of carnations who are inland residents never see in their own plants. Of course, the beneficial climate is ably seconded by good culture, and the result was strikingly illustrated in the recent show.

I believe that many of our English growers use salt as a spray, and a very useful spray it is. It is invaluable for keeping down red spider and for keeping fungoid diseases at bay. With the American growers it is a standard remedy, and this is solid proof of its virtues, surely.

One was also glad to note the continued success of many of the older favourites. For a blush coloured variety, it was Enchantress everywhere, and it will be long before her glory is eclipsed. Harlowarden showed up well again in the crimsons, though President was shown in fine condition by the Guernsey folk.

Mrs. T. W. Lawson still continues to rank high both in competition and in popular favour, though the new Aristocrat will doubtless prove a formidable rival.

Britannia was foremost for the thirty-six blooms of scarlet, but in the eighteens Robert Craig was shown in very good form, gaining first and third places. Winsor made a remarkable debut. Its glorious triumph at the Toronto Show at the beginning of 1907 was continued at Regent's Park, where it was first in the light pink classes, beating even the favourite Mrs. Burnett. It also ranked highest among those which were awarded the Certificate of Merit.

Beacon was shown in good condition, but will, I believe, improve as it becomes more popular. Rose Pink Enchantress has made good its American reputation, and will doubtless become a standard variety in the near future.

Melody completed the quartette which gained the coveted distinction; it is a soft blush colour, and is accredited with being "very free-flowering." There is evidently yet no white to surpass the favourite trio Lady Bountiful, White Perfection, and Improved White Lawson, at least, if there is, it has yet to show itself.

The new American variety Sensation promises to be more than useful. It is a beautiful bright cerise in colour, the blossoms are well built, non-bursting, with long, strong stems, and exceedingly free.

One of the Michigan growers has a new seedling of much promise. It is a cross between Enchantress and a Red Seedling, and partakes closely of the habit and colour of Enchantress. The blossoms are very large, and, unlike Enchantress, which loses its colouring as it ages, it deepens in hue. It is free and very fragrant. Another new American which has been certified at New York and Indianapolis, is Mabelle. This is a peculiar yet charming shade of pink, with a faint yellowish tinge; it is a first-rate grower, strongly scented, and giving an abundance of good-sized blossoms on long, stiff stems. It is spoken of as being uninjured by the brightest sunshine, and comes in flower early.

Many other novelties are undergoing trial, some of them on this side of the water, including Red Chief, a bright-hued variety, favourite with some American growers already. Others will be seen at the next American Show, which will be held at Washington.

Already the perpetual carnation has a strong hold on the horticultural world, and its fame will increase rapidly during the next few years. For private gardens and for market culture there is nothing much more desirable, or which is in more constant demand. One notices the lasting properties of the blossoms when cut, and as the flower-buying community fully realises this, they will purchase carnations in preference to cheaper flowers. Even now the sale of cut carnations reaches goodly proportions, and, like the American trade, it will grow and increase rapidly, especially as this is the "day of the cut flower," and the plant trade is practically a decaying industry, at least at the present day.

P. S. HAYWARD.

NEW PLANTS, ETC.

◆

ODONTOGLOSSUM MACNABIANUM.

This splendid hybrid, from O. Harryanum and O. Wilckeanum albens (figured on p. 57), is a fine addition to the already large group descended from the former parent. The flowers are of large size, and the ground colour is pale yellow, this showing through between the heavy red and red-brown blotches in the form of irregular lines and marks. The lip is flat, and has a large white apex, but the base is prettily marked with purple and red. The plant is a strong grower, and it carried a spike of twelve flowers. F.C.C., R.H.S., January 14. Messrs. Sander and Sons, St. Albans.

ODONTOGLOSSUM BINGELIANUM.

Another grand odontoglossum, but of unrecorded parentage. The flowers are large and of particularly fine shape, as shown by the illustration. The colour is soft greenish-yellow, heavily spotted and blotched with rich red-brown. The lip has a white apex, but is marked with red-brown at the base. F.C.C., R.H.S., January 14. Mr. H. Ballantine, gardener to Baron Schroder, The Dell, Egham.

CYPRIPEDIUM SULTAN.

This imposing variety was raised at Westonbirt by crossing C. Mons. de Curte with C. Milo Westonbirt var. It has flowers of largest size, well proportioned, and substantial. The broad petals are green and brown, the latter shade being very bright; the dorsal sepal is yellowish-green at the base and white at the apex, the green area being heavily spotted with dark purple. The lip is brown, with green shading, and the whole flower presents a burnished or varnished appearance. F.C.C., R.H.S., January 14. Mr. H. Alexander, orchid grower to Major Holford, Westonbirt, Gloucester.

CYPRIPEDIUM MINOS YOUNG'S VAR.

A beautiful cypripedium, and one that was granted an Award of Merit in 1903. It is the result of crossing C. Spicerianum with C. Arthureanum. The dorsal sepal is particularly fine, broad, rounded, white, marked with rosy-purple, and with a greenish base; the petals and lip are yellowish-green, heavily shaded with brown. F.C.C., R.H.S., January 14. Messrs. J. and A. McBean, Cooksbridge, Sussex.

LÆLIO-CATTLEYA CORUNNA.

A shapely and effective hybrid of unknown parentage. It has rosy-purple sepals and petals, and a rich crimson-purple lip, with orange and gold veinings in the throat. A.M., R.H.S., January 14. Major Holford.

Naming Trees at West Ham.—At the instance of Mr. A. Jerrold-Nathan, the chairman, the West Ham Park Committee have decided to label the various trees and shrubs in the park with their botanical and proper names.

NEW BOOKS.

SWEET PEAS AND THEIR CULTIVATION.

By Charles H. Curtis, F.R.H.S. (W. H. and L. Collingridge, 148 and 149, Aldersgate Street, E.C.) Price, 1s. net, by post, 1s. 2d.; cloth, 1s. 6d., by post 1s. 8d.

Sweet peas have become so enormously popular of late years that their cultivation has increased by leaps and bounds, and as the result there are but few happy in the possession of gardens who do not endeavour to produce an abundance of their fragrant and exquisitely coloured blossoms. With the immense increase in the cultivation of these charming flowers a handbook wholly devoted to them has become a necessity, and fully understanding the aid cultivators generally are likely to require, the perusal of "Sweet Peas and their Cultivation" has given us much pleasure. It is pleasant to read the brightly written sketch of the history and development of sweet peas, and also the advice given on the various details that must have attention to ensure success. But it gives us much pleasure to find, as we anticipated would be the case, a work wholly free from the defects of shilling gardening books devoted to special subjects. The author has appreciated his responsibilities, and taking full advantage of his exceptional opportunities for observation, he has known exactly what his readers would require, and has evidently made strenuous efforts to provide what they would be likely to need. Having a thorough knowledge of the cultural requirements of sweet peas, and a practical acquaintance with the numerous varieties, he has been able to tell his readers all that it is necessary they should know to obtain successful results. What is not less important, possessing literary skill of a high order, he has been able to give the information contained in the book in such a manner that the readers will have no difficulty in understanding it.

The book opens with a chapter on "The Sweet Pea Cult," which affords interesting reading, and this is followed by a chapter in which the history and development of sweet peas is admirably sketched. The remaining part of the book is devoted to cultural matters, and in the several chapters the reader will find all the information he could possibly desire relating to the growth of sweet peas and to the selection of varieties for beautifying the garden, for the decoration of the home, and for winning prizes at exhibitions. While every chapter should have careful consideration, we would suggest that special attention should be given to those devoted to "Soil Preparation," "Seeds and Seed Sowing," "Staking and Tying," and "Some Points for Exhibitors." Fungoid diseases and insect pests are described, and illustrated, so that the reader is not only, with the aid of the book, placed in a position to select the finest varieties and grow them to a high degree of perfection, but he is given assistance in combating those enemies that, were they allowed to go unmolested, would greatly hinder him in his efforts to obtain success of a high order.

The book contains numerous illustrations, and we reproduce the one of a clump of Dora Breadmore sweet peas as indicating their excellence.

SWEET PEA DORA BREADMORE.

Sown January 11, under glass, cut back twice during summer. Photographed September 7.
(From "Sweet Peas and Their Cultivation.")

A CONCISE HANDBOOK OF GARDEN ANNUAL AND BIENNIAL PLANTS.

By C. M. A. Peake. (Methuen and Co., Essex Street, Strand, W.C.) Price, 3s. 6d. net.

A dainty book, elegantly printed and prettily illustrated, and containing much useful information on the various classes of annuals and biennials, and on many of the perennials that can be readily raised from seed. The author has missed the opportunity of producing a really good book on annuals and biennials by including a considerable number of perennials, and failing to indicate the duration of a considerable portion of them. In a selection of half-hardy annuals at the beginning of the book there is a list of "half-hardy annuals," in which ageratums, hybrid begonias, cobæas, dahlias, and eccremocarpus are included. As annuals are now grown largely for exhibition, it is of much importance that in a work devoted chiefly to them the arrangement should be such as to avoid the risk of the reader being mistaken as to the duration of the plants included. We suggest that in a future edition the author, in process of revision, very clearly indicates the duration of the whole of the plants he mentions. With this improvement the book would have its usefulness materially enhanced.

MODERN FRUIT CULTURE.

(George Bunyard and Co., Lim. Maidstone.) Price, 1s.

In this brochure Messrs. G. Bunyard and Co. have reprinted the cultural articles contained in their fruit catalogues, and thereby have been able to present them in a more convenient and handy form. There are several new chapters, notably one in which the root pruning of fruit trees is described at some length by Mr. George Bunyard, V.M.H., and notes on the cultivation of roses, which, by the way, receive much attention at the Maidstone establishment.

THE GARDEN ANNUAL, 1908.

Edited by W. Robinson. ("Gardening Illustrated" Office, 17, Furnival Street, Holborn, E.C.). Price 1s.

The "Garden Annual," as so well known, is devoted almost exclusively to the directories of gardeners and the nursery and seed trades. It is not less well known that these directories are remarkable for their fulness and accuracy, and it would be difficult to give higher praise to the issue for the current year than to say that it fully maintains the high character of its predecessors. The several lists bear evidence of careful revision, and the work is in every way thoroughly up to date and trustworthy.

HORTICULTURAL DIRECTORY.

("Journal of Horticulture" and "Poultry" Office, 12, Mitre Court Chambers, Fleet Street, E.C.) Price, 1s.

As the "Horticultural Directory" has a history extending over nearly half a century it would be difficult to say anything new with regard to it. But we can say without experiencing the slightest difficulty that it fully maintains the high character which has rendered it popular for so long a period. In addition to the full directory of the nursery and seed trades in the United Kingdom, there are lists of the principal nurserymen and seedsmen on the Continent of Europe and in the United States and the Colonies. There is a list of botanical gardens in the British Empire, and a directory of horticultural builders, engineers, and sundriesmen.

L'HYBRIDATION DES PLANTES.

By Raphael de Noter. (Charles Amat, 11, Rue Casette, Paris.) Price, 2.50 francs.

An excellent work on the hybridisation of plants by one of the leading French authorities. In the first division of the book the reproductive organs of the plants are described, with the aid of well-executed diagrams, and full information is given on the several operations necessary to ensure success in the fertilisation of flowers. The second part is devoted to the more important of the several classes of plants that are in general cultivation, and in addition to the descriptive matter suggestions are made for their improvement. The book, which is in French, is freely illustrated.

SWEET PEA AUDIT.

For permission to publish the following Audit of the Sweet Pea Show held in London, 1907, prepared by Mr. C. H. Curtis for the National Sweet Pea Society, we are indebted to the committee of that body:—

Never was the work of compiling the Audit of our great London show such a tiresome business as in 1907. The increased number of classes, larger number of competitors and bunches, bigger attendance of visitors, and the comparative crowding necessary to get the whole of the exhibits into the great hall, all tended to make the difficulties of the auditor greater than ever before. Then, too, many competitors appeared to consider that as long as the name cards were duly inscribed and placed somewhere on the table, that was sufficient, and in this connection the competitors in the "Small Growers'" section and "Single Bunch" classes were the greatest sinners. In many instances comparisons had to be made ere the proper name of the variety could be arrived at. Remembering that an Audit is one feature of the society's work, exhibitors should do their best to assist by taking care that their name cards are legibly inscribed and properly placed in position.

Probably, indeed very possibly, future Audits will be conducted on different lines to this and the preceding ones. Or, rather, the varieties named for the Audit Class may be the "bests" as shown by an Audit of only those exhibits in classes where there is no restriction as to varieties. This, however, is a matter for further consideration, but it has been raised by the suggestion that it is possible to force almost any variety to the top of the Audit, or thereabouts, if sufficient motive power, in the shape of big money prizes, is provided.

But let us to the Audit itself. The first comparisons are as follows:—

Year.		Classes.	Exhibits.	Bunches.	Varieties.
1907	......	81	651	2390	205
1906	......	73	416	1949	152
1905	......	36	273	1826	119
1904	......	29	258	1561	107
1903	......	28	128	991	90

These figures show a big increase in classes, a large addition of exhibits, and about 400 more bunches than at any previous show. There was also an increase in the number of varieties exhibited, and though this was to be expected at such an enlarged exhibition, there is nevertheless a feeling of regret that the increase in this respect is so large. We do not improve as one could wish, and an average of 11.65 bunches per variety is a poorer showing than the 15.34 bunches per variety in 1905; that is, if the reduction of varieties is to be regarded as progress. Some may urge that the lower average of bunches per variety is progress, because it indicates activity on the part of raisers and argues for a wider interest and lack of monotony in the show.

The averages of bunches per variety, as shown by the various audits, are:—11.01 in 1903; 14.58 in 1904; 15.34 in 1905; 12.82 in 1906; and 11.65 in 1907.

Total Bunches...	2,390
Total Varieties	205

The general Audit of 1907 presents a very different appearance to that of 1906. Helen Lewis and Countess Spencer, which were ninth and tenth in the latter year, now stand at the top of the list; John Ingman comes up from thirteenth place to third position; Dorothy Eckford and King Edward VII. come from first and second places to fourth and sixth respectively, but they easily maintain their places as the best varieties in their colour classes, with 110 and 92 points as against 121 and 97 in 1906; the rise of Queen Alexandra and the exhibition of many seedling white varieties may be considered as partly answerable for this alteration of the position of such excellent varieties, but probably the chief reason is to be found in the great advance in popularity of the waved varieties during the year.

Helen Pierce has jumped from 33 points to 97, and now takes fifth place. Mrs. Collier has taken a big leap upward; Black Knight keeps a steady position; Gladys Unwin falls away somewhat, and Miss Willmott drops from 72 points and fourth place in 1906 to 32 points and twenty-third place in the present audit. Nora Unwin takes a good position, with 81 points, the same number that Gladys Unwin had in 1906. Paradise, Frank Dolby, Mrs. Hardcastle Sykes, Henry Eckford, and Mrs. Alfred Watkins are varieties that have come forward with a rush. Another interesting point is that no fewer than thirty-one unnamed seedlings were exhibited. The substantial positions taken by Shasta, America, and Janet Scott are evidence that these three good garden varieties are favourites with many other growers than the writer.

Total Bunches	378
Total Varieties ...	102

The Audit of the first prize exhibits includes 378 bunches and 102 varieties, as against 261 bunches and 64 varieties in 1906. Varieties do not invariably hold the same relative positions in the general Audit and the first prize Audit, and this year the differences are very marked. Helen Lewis holds first place in each case, but here Nora Unwin displaces Dorothy Eckford as the best white, though with insufficient points to triumph altogether, the points being 110 plus 9, equals 119 for Dorothy Eckford, and 81 plus 20, equals 101 for Gladys Unwin. Next year another young lady will be striving for premier place as the best white—which will win? Plenty of opportunities for comparison are afforded by the two Audits, such as those between Mrs. Alfred Watkins and Mrs. Hardcastle Sykes, Romolo Piazzani and Navy Blue, but these can be easily made by the reader.

A most interesting point is the average number of bunches per variety in the first prize Audit. The figures are as follows:—

Year.		Bunches.		Varieties.		Average Bunches per Variety.
1907	...	378	...	102	...	3.70
1906	...	261	...	64	...	4.07
1905	..	244	..	73	...	3.34
1904	...	217	...	62	...	3.50
1903	...	216	...	71	...	3.04

This is not so good a showing as in 1906, but nevertheless a good one compared with previous years, and also relatively to the averages in the general Audit. It suggests that the most successful growers pin their faith to a moderate number of varieties for exhibition purposes.

BEST VARIETIES.

The varieties from which those who compete in the audit class in 1908 must make their selection are given below, and in the subsequent columns are given the points these varieties gained in the general Audit and first prize Audit and also their position in the respective colour classes, as shown by the votes recorded in the returned classification lists:—

Colour and Variety.	General Audit.	Prize Audit.	First Position in Classification list.
White—Dorothy Eckford	110	9	1st
Crimson and Scarlet — King Edward VII.	92	12	1st
Cerise—Coccinea	12	3	1st
Rose and Carmine—John Ingman	115	13	1st
Pink—Countess Spencer	130	19	1st
Blush—Mrs. Hardcastle Sykes	31	8	1st
Blue—Navy Blue	37	3	3rd
Yellow Shades—Mrs. Collier	73	9	1st
Orange—Helen Lewis	135	24	1st

Fancies—Sybil Eckford	35	1	2nd
Marbled—Helen Pierce	97	10	1st

DOUBLE-FLOWERED EPACRIS.

This epacris, now known as Epacris purpurascens flore plena, though it was first distributed as E. onosmæflora flore plena, differs from all the other numerous forms of epacris in the flowers being double. As far as I know the double-flowered variety of the common ling or heather is the only heath we have with duplex blossoms, so that this feature is less pronounced among the Ericaceæ than it is among many classes of plants.

The epacris in question also differs from the ordinary garden forms in being of stouter growth, and with the young shoots of a more succulent character. These shoots are thickly clothed with leaves, from the axils of which the flowers are produced. Individually they form, when fully expanded, little white rosettes, but in the bud state they have a slight purplish tinge, which can always be seen at the back of the petals. These flowers form a closely packed mass for a considerable distance along the shoots.

Introduced from Australia about thirty years ago, this epacris was first sent out in 1883, and in those days was thought highly of, but now it is very rarely seen. Its cultural requirements are the same as for epacris in general, except that most of the shoots, being very stout and succulent, do not strike root readily. The best way to get suitable cuttings is to put a plant or plants into a little warmer structure than that in which epacris are usually kept. This will induce weaker growth, and the shoots so obtained are not at all difficult to strike, provided they are dibbled into well-drained pots of sandy peat, sifted fine, and pressed down very firmly. After being watered, they must be covered with a bell glass, and given a shaded position in a house kept at the same temperature as that in which they have grown.

W. T.

Manuring Sweet Peas with Superphosphate. — No, it does not mean, "E. J. K." (page 4), that I am about to commence the sale of concentrated plant foods, for if I did my generous recommendations would kill all my customers' plants, and they would want to kill me. During my journalistic experience I learned (and it only took me three days to do it) to put every error, frivolous or serious, big or little, down to the printer, and behind that mysterious individual I shield myself now. That maxim should have read: Use 7lb. of superphosphate to the square rod, in which condition it is good, and, in conjunction with the others that accompanied it, will help the sweet pea grower on towards success. I try to find consolation in the reflection that very few people will feel disposed to spend the money necessary to apply a dressing at the rate of 7lb. to the square yard.—HORACE J. WRIGHT.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

GENERAL REMARKS.—The exceedingly changeable weather conditions during the past three or four weeks—and from general appearances these conditions are likely to continue for awhile—has restricted the general work in the orchid houses. Opportunity should now be taken to attend to any cleansing that may be necessary. A more than ordinary amount of artificial heat is required, even to maintain the minimum temperature in each division, and this, with the drier atmosphere created will have a tendency to aid insect life, especially red spider. Close observation is therefore necessary, and when the pest is found steps must at once be taken to check it. There is no better method of preventing the spread of red spider than to carefully sponge the leaves. Small yellow thrips are perhaps the worse pests the orchid grower has to contend with, especially the species which attack cypripediums; I never hesitate to dip these plants at any season of the year, where thrip is found in the axils of the leaves. Where plants have to be dealt with that have become so infested that the foliage is disfigured, the best method is to dip at intervals of a week for about a month, and then fortnightly, until satisfied that the plants are free from the pests. For dipping and spraying purposes we use XL All. Prevention is always better than cure, and we find it advisable to spray the plants once or twice a month in all the warm divisions, choosing a day when the outside conditions are favourable for the purpose.

HEATING.—The varied facilities provided in the shape of boiler power and piping naturally have their advantages and disadvantages, which very materially affect the results produced in the cultivation of orchids. It is now many years ago since I drew attention in these columns to the necessity of the provision of ample piping in every department of our orchid houses. I am still of opinion that sufficient care has not yet been generally observed in this matter. The horticultural builder mostly sticks religiously to his hard and fast rules, i.e., that the amount of piping specified is ample. The fact that the greater amount of piping used will give the necessary heat with less firing and far less deplorable results is generally overlooked. Growers and their enthusiastic employers have of late years given more attention to this matter, but there is still plenty of room for improvement, and I would impress any who may be contemplating the erection of houses to see that more than sufficient piping is used. The initial outlay may be considerable, but it will soon be balanced by the saving in fuel.

WATERING.—One of the greatest difficulties during the prevalence of unfavourable outside conditions is the proper application of root moisture. There may not, perhaps, be so much judgment required in absolutely hard weather as is necessary during lengthy periods of foggy or dull weather. When there is obscured light the drying conditions are naturally reduced, and a general tendency to stagnation is prevalent, and I always feel that with such conditions one cannot be too careful. With low temperature plants are not nearly so liable to injury when dry as when they are in a wet state at the roots. Care must also be observed that the water used is, if possible, a degree or two higher than the normal temperature of the house. After heavy rains, or where snow water is finding its way to the rainwater tanks, it will be found that the temperature of the water becomes very low, and before using such water sufficient hot water should be added to raise the temperature to the required degree.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

FORCING PLANTS.—From this time onward forced plants will come forward well, and those who have been able to wait so long before beginning will be repaid for the delay by the better quality of flowers produced. To those who have plenty of convenience for forcing the work is easy, but in many cases makeshifts have to be used, and to those who have very little choice it is far better to begin with a comparatively low temperature than it is to give much heat, as the latter frequently defeats the end in view entirely, and invariably tends to the production of flimsy flowers that are all but useless for cutting. Shrubby plants, such as azaleas, staphyleas, guelder roses, and lilacs enjoy a moderate temperature in a house where they can be freely and frequently syringed; spiræas cannot be given too much water, they revel in it from the time they begin to grow.

WINTER-FLOWERING CARNATIONS must be struck early to obtain good plants by the autumn; some growers have already secured an early batch, but successional plants are very useful when room can be found for them, and the present is an excellent time for putting in the cuttings. As most varieties will now be producing plenty of side growths the shoots should be pulled out in the form of pipings, and the knife not used. Use sand freely in the cutting pots, and make each piping firm; water well in, and after having allowed the pots to drain, plunge them in a fairly brisk hotbed. The tops should be kept cool, and the soil warm.

ASPIDISTRA LURIDA VARIEGATA.—No garden should be without a stock of this most useful plant, but, vigorous as it is, fresh plants have to be established. It increases readily by division, and when given a good start, in smart bottom heat, it makes roots rapidly. The present, therefore, is a good time to propagate. A light and porous soil should be used, one containing a good portion of lime rubble being preferable; the pots used should be well drained, as copious waterings are essential when the plants are well rooted. I find that three-inch pots are the most convenient to use, as the plants can be placed directly from these into 4½-inch pots, which are the most serviceable for furnishing. The crowns, or roots, should be broken up into pieces suitable to the size of pots, and pressed in firmly. Little water will be required until growth is active, and at no time until the pots are well filled with roots should liberal waterings be given. Then, however, they will demand abundance, and be benefited by occasional waterings with soot water.

SOWING SEEDS.—For the majority of plants it is full early for sowing seeds, but some things, such as hybrid streptocarpuses, Saintpaulia ionantha, tuberous begonias, and others which are treated as annuals, if allowed plenty of time to grow, can hardly be sown too soon if space and other conveniences can be given them. The above have very fine seeds, which must be sown on the surface in pots carefully prepared by being well drained to within two inches of the rims, and filled up with a sandy soil, which should be quite level, and well watered before sowing the seeds. Place the pots in heat, half plunging them in the hotbed material; cover with glass, and shade always during the day. The streptocarpuses are especially impatient of sunlight, and should never be neglected in the matter of shading.

LILACS.—Very few shrubs respond so readily to a genial temperature as the lilac. Where large bushes of the ordinary white lilac are obtainable, this is a good time to lift them carefully, tie their branches closely together, and set them in any warm greenhouse with a gradually increasing temperature; cover the roots with soil, water freely, and keep the tops syringed daily until the buds burst into leaf. If the white variety is not available, the ordinary purple-flowered sorts are very easily blanched by means of a thick shading. The Persian variety is most useful, and may be kept for several seasons to a serviceable size by giving it a little extra attention during the summer.—T. B. Field, Ashwellthorpe Gardens.

STOVE PLANTS.

PROPAGATION. — To obtain useful crotons and dracænas early in the season, for table decoration or for single-stemmed specimens, I prefer propagation by notching and mossing. For this purpose plants that have lost their lower foliage, but have good healthy tops, are selected. Immediately below the healthy foliage a notch is made on either side of the stem, and the bark removed. Having secured the plant to a stake, some damp moss is placed around the stem and tied firmly. If ordinary moss is used I prefer to mix it with cocoanut-fibre refuse or fine peat and silver sand. The moss must be kept moist, and as the roots appear another layer of moss is added. For the largest and most valuable specimens I prefer to split a six-inch pot in half and tie this around the stem, filling it with potting compost into which the roots very readily run. The tops may be separated from the parent plants as soon as the small pots are filled with roots, the stem being cut through gradually at intervals of a few days. After separation syringe and shade as necessary.

POTTING.—Although the season is not sufficiently advanced for potting in general, some of the more free-rooting subjects may be treated in order to save time later on when so many plants require attention.

ALLAMANDAS.—Those plants that have had a season of rest may be pruned well back into the hard, ripened wood, and potted almost immediately afterwards. Before removing the soil from the roots to prepare for potting, the plants should be wholly immersed in a tank of tepid water, where they may remain until the soil is thoroughly moist; then allow them to drain for a few days. Allamandas succeed best in a compost of good fibrous yellow loam, to which are added a sprinkling of half-inch charcoal and lime rubble, with about a sixth part of well-decayed manure and enough silver sand to keep the compost porous. Use well-drained clean and dry pots, according to the size of the plants, and pot firmly in order to secure short-jointed wood, as this gives the best display of bloom. After potting the plants may be placed in position, and given enough water to settle the soil. Syringe occasionally to encourage growth, but give very little water until the roots are active. Carefully train the shoots to the wires as they become long enough to tie, because if neglected they are likely to become injured.

CALADIUMS.—Early batches of these handsome foliage stove plants never fail to command admiration. We select the earliest ripened tubers, and start them into growth by placing them two inches apart in shallow seed boxes, which have been previously filled with a mixture of silver sand and oak leaf-soil in equal parts. The tubers are lightly covered, and the surface sprinkled with sand. The boxes are placed in a light position in the stove. Only a light damping as the surface becomes dry is needed until root action has commenced. The tubers should be potted up before the roots become entangled. For the earliest batch I prefer small pots, as the plants are then serviceable for house or table decoration. If large specimen plants are desired they must not be allowed to become root-bound, as this retards progress.

GENERAL REMARKS.—During January very little ventilation is required in the stove; if, however, the temperature rises above the required degree from sun heat, and the atmosphere is clear, a little air given judiciously is beneficial. Be careful to close up the house again early, before the sun looses its power, or a waste of fuel will be the result. Continue syringing and damping as previously advised, and towards the end of the month the night temperature may be raised to 68 degrees, with 5 to 10 degrees higher during the day. Pots or soil used for potting stove plants should always be at the same temperature as that of the stove.—John Donoghue, Bardon Hill Gardens.

THE FLOWER GARDEN.

WINTER.—Of late the weather has been very severe, and I fear unprotected tender shrubs and plants will suffer badly. On the slightest rise of temperature above freezing point at once remove temporary protection and let frost out. Many lessons may have been learned during severe weather, if observation has been made. The pleasing effect of the various brightly-coloured barks of shrubs and trees, especially when looking across stretches of water or ice, may have been noted. The scarlet and golden willow, or silver birch, scarlet dogwood, Rubus phœnicolasius in a fairly warm but prominent position, maples in variety, and others, with the sun shining on them, have had an almost dazzling effect. Note should be made of any spot available for planting these when weather becomes suitable. The sea buckthorn is also suitable, and if a green patch or two is desired, gorse or broom may be used.

ROCK GARDEN.—Pay attention to rock gardens, as cleaning and any top-dressing may be done now; pockets from which any plant has been removed should be cleaned out and refilled in readiness for planting. Make sure all plants are correctly named.

WINTER FLOWERS.—A plant that is very acceptable for its sweet-smelling flowers at this season, yet which should not be planted in a mixed collection, but in a spot where it may ramble, is Tussilago fragrans; one can only recommend it for its sweet early flowers, as if once planted where it grows freely it is difficult to eradicate. Hamamelis, with their early flowers, should be planted more than they are; the individual flowers are not very noticeable, but in the aggregate, on a well-flowered tree, are very beautiful.

CLIMBERS.—Flowering and ornamental climbers on arches, pergolas, and sheltered parts of walls should be attended to towards the end of the month, and any old or dead wood be cut out, pruning done, and growths tied in, in readiness for the ensuing season. When pruning pay proper regard to each species and variety; with clematis, those that flower on the young wood, such as Jackmani, Madame E. Andre, Star of India, rubella, etc., will require more severe pruning than those that flower on the previous season's growths, such as Lady Londesborough, Miss Bateman, The Queen, Duchess of Edinburgh, Lucy Lemoine, Albert Victor, etc. The smaller flowering montana type should have an abundance of room, and receive practically no pruning. Jasminum nudiflorum as it passes out of bloom should be pruned, laying in young wood where space permits. With roses, if the old wood was not removed after flowering last summer, this should be done now, replacing it with strong young growths. On cold or exposed positions it is better to postpone pruning until next month, as only on warm sheltered positions is it safe to prune thus early, lest early growth should ensue, and then later frosts come and kill or damage it.

PELARGONIUMS.—If the stock of bedding pelargoniums is insufficient cuttings from the largest autumn-struck ones that have made sufficient growth may now be put in; do not cut small or weakly plants too low, or they may not be sufficiently large when required for bedding. Cuttings may be inserted either singly in small pots or several in larger ones. Personally I prefer single pots, as then there is no damage to the roots when potting. The object should now be to obtain sturdy plants. A temperature ranging from 55 to 65 degrees is suitable for rooting them in, after which a lower one may be given. Use sandy soil, and keep it just moderately moist; shading is quite unnecessary, but do not place the cuttings in a draughty place. The variety Paul Crampel seems to be becoming a very general favourite among the scarlets.

SEEDS.—Many seeds may now be sown, such as Acacia lophantha, eucalyptus in variety, ricinus, pentstemons, antirrhinums, dianthuses, aquilegias, Papaver nudicaule, begonias, etc. Acacias, cannas, ricinus, eucalyptus, and begonias must have a fairly high temperature, the others not so high. Great care must be taken; for the smallest seeds no covering of soil should be given; sow in pots, pans, or boxes, with a layer of leaves, old moss, or roughest of soil over the drainage, then fill with sandy soil, make firm with an absolutely level surface, give a good watering, and allow the pots to stand until well drained, when a light sprinkling of sand may be given, and the seed sown on it. Cover with a sheet of glass, place in a moist atmosphere, and keep well shaded. Never attempt watering overhead, but allow water to soak up from a pail or tub of water. The larger seeds should be just covered with soil and a sprinkling of sand. Cannas and some other large and very hard seeds germinate much better if first soaked in warm water for twenty-four hours, and then have their outer shell just filed through with a sharp fine file; in fact, unless something of this sort is done they often fail to germinate.—E. F. Hazelton, Knowsley Gardens.

HARDY FRUITS.

PRUNING.—During frosty weather it is not advisable to prune fruit trees, but as soon as the frost is out of the wood the work should be pushed forward as fast as possible. When pruning plum trees on walls I prefer the trees to be trained fan-shaped, retaining plenty of young shoots here and there for the purpose of replacing old worn out branches. Two-year-old wood invariably produces the finest fruits. Shorten all foreright growths back to within a few eyes of the base; those intended for leaders and for fruiting in between the main branches, etc., should be shortened back to within fifteen inches of the last year's wood. See that the ties and fastening do not pinch the bark, and be careful not to bruise the wood with the hammer. Any old worn-out trees should be grubbed up and replaced with young, healthy, fruitful ones. Young trees that have been planted two or three years and which are growing too coarse and strong to be fruitful, should be lifted and replanted afresh, shortening a few of the strong roots, and relaying them in a little fresh, sweet soil, and then filling up with the staple. I am not a believer in too many varieties, especially if wall space is limited. Do not omit to save grafts, if these are required. They should be tied up in bundles, correctly labelled, and heeled in under a north wall till the season arrives for grafting.

MANURING.—Advantage should be taken of frosty weather to wheel manure on to all fruit quarters and borders where such is needed; short, well-rotted farmyard manure is the best for most purposes. On currant and gooseberry quarters, when the frost is out of the ground, it may be lightly dug in, taking care not to damage the roots, but on newly-planted plots, where it is intended to grow a crop of vegetables between the rows digging may be deeper. A good mulching of manure over the roots of black currants will be found very beneficial, and will assist the bushes to produce stronger wood and reduce the bud mite.

STRAWBERRIES AND RASPBERRIES.—Those intending to make fresh strawberry and raspberry beds should get plenty of manure wheeled up in readiness for trenching when the frost is out of the ground. Trenching early gives the soil a better chance to become consolidated before planting, especially on light soils. Do not forget to examine newly-planted beds after the frost leaves the ground; the plants may have been somewhat lifted and require a good firm treading over the roots. Forced strawberries, if properly hardened and planted about March or April, make fine fruiting plants the following year, and some varieties produce a nice crop during the autumn. Viscomtesse Hericart de Thury and Royal Sovereign both fruit well if carefully attended to. Those who have not grown Givon's Late Prolific should certainly do so; for late use it is the best I have ever grown, the fruits are plentifully produced, and large.

ORCHARD TREES.—These are apt to be overlooked and neglected, but those who make it a practice of attending to them every two years, or annually, will be well rewarded for the amount of trouble and attention given. The heads should be kept somewhat open to allow of light and air reaching the interior of the trees. All cross branches should be cut out, using a saw for the work. Some of those interlacing should be removed, so that instead of the heads being thickets of useless wood and the crops of fruit small and scabby, serviceable fruits will be produced. Good soakings of farmyard liquid manure will greatly help the trees if judiciously applied over and about the roots at this season of the year; it may be given at a much greater strength now, but whatever is applied, enough should be given to penetrate the soil to a considerable depth.

FRUIT ROOM.—The stored fruit should be examined weekly, and any showing signs of decay should be picked out and used at once; do not handle the good fruits if possible, as the least bruise may cause rotting. Air should be admitted on favourable occasions to keep the room sweet. Do not allow hay or straw to remain inside the room till it becomes musty. Our Cox's Orange Pippins are nearly over, and those to follow are Baumann's Red Reinette, Duke of Devonshire, Court Pendu Plat, Scarlet Nonpareil, and Lord Burghley, while of kitchen apples we have Lane's Prince Albert, Bramley's Seedling, Old Round Winter Nonsuch, Dumelow's Seedling, and Anne Elizabeth all keeping well.—H. MARKHAM, Wrotham Park Gardens.

THE UP-KEEP OF BOUNDARY FENCES.

As the Board of Agriculture has frequently received inquiries as to the legal position in regard to the repair of boundary fences, it has now stated in its "Journal," in general terms, the legal position in this respect.

At common law the owners and occupiers of adjoining fields are not bound to fence either against or for the benefit of each other, but each person is bound to prevent his cattle or other animals from trespassing on his neighbour's premises.

A liability to repair a fence can only be created by Act of Parliament, as is done in certain Inclosure Acts and Railway Acts, by prescription or by some agreement or covenant which constitutes a binding contract between the parties. Evidence of such an agreement may be implied by the fact that a person has repaired a fence when called upon to do so; but it depends on the strength of such evidence and the circumstances under which the repairs were made whether it will be sufficient to establish a liability to repair. The fence may have been erected by the owner on his own land to prevent cattle from straying upon the property of a neighbour, and the mere fact that it had been repaired by the owner is not sufficient to establish a liability on his part to keep it in repair, for the habitual repair of a fence is perfectly consistent with the contention that the repairer has kept his fence in order for his own purposes, and is no evidence of any obligation to repair it for the benefit of a neighbour.

To prove a right by prescription very similar evidence is required, showing the uninterrupted enjoyment of the alleged right to enforce repair for a period of forty or in some cases twenty years.

The Horticultural Club.

"RECENT ADVANCES IN PLANT BREEDING."

On Tuesday, the 14th inst., after the usual monthly dinner of this club, Professor J. B. Farmer, M.A., F.L.S., taking the chair, Mr. E. A. Bunyard addressed the meeting on the above subject, with special reference to Mendel's work, pointing out the immense advantage which the publication of the Mendelian experiments, and the law of heredity which they indicated, had given to selective culture of every kind, the old-fashioned guesswork, with all its uncertainty and consequent loss of time and labour, being now largely replaced by the knowledge that, given a conjunction of certain characters by crossing or hybridising, certain definite results were practically sure to appear in their progeny.

Mr. Bunyard, in his experiments, had followed Mendel's example by selecting the pea tribe as material, and found the results fairly confirmatory; he had, however, conceived the idea that the so-called dominant and recessive characters were not necessarily of a distinct nature. Taking, for example, wrinkled and round peas, or white, pink, or blue flowers, he was of opinion that the difference was merely one of development, the wrinkled peas being an advanced form of the round, while as regards colour it was frequently to be noted that the unopened flower buds might be of a recessive tint, and the dominant tint developing gradually as the flowers matured, passing from white, through pink, to bluish tint as they faded. Mr. Bunyard illustrated his remarks in a very clear manner by means of black and white cardboard discs, the black representing dominant and the white recessive characters, each of which was present in mixed offspring, either in a latent or patent form, and subsequently made their appearance in F2, or the next generation, in strict conformity with the law of chance which underlies the Mendelian law. Thus if 200 wrinkled peas, for instance, be thoroughly mixed with 100 found ones in a bowl, and taken out in pairs by a blindfolded person, those pairs would come out in definite ratios of round and round, wrinkled and wrinkled, and wrinkled and round, precisely in the same proportions as they would reappear by the Mendelian theory and experiments. This, indeed, is the logical result to be expected from the segregation of the two different character potencies existing both in the pollen grains and in the ovules of the plants concerned.

In the subsequent discussion, in which Professor F. Farmer, Messrs. Darbishire, Bilney, Cuthbertson, and Druery took part, the value of Mr. Bunyard's observations was fully recognised, and many interesting points in connection with the subject brought forward. Professor Farmer pointing out the probable extreme complexity of the units, which form what are termed characters, Mr. Cuthbertson adding some interesting remarks anent his own experiments, and citing the singular fact that wrinkled peas appeared to be correlated with lilac or purple flowers. Mr. Druery considered that much of the literature relating to the Mendelian principles ignored to too great an extent the possible disturbing influence of the spontaneous adoption of new characters due to sudden "sporting," since any tendency in this direction would be apt to upset results entirely.

Mr. Bilney referred to hybrid orchids as evidencing, in the first generation, intermediate characters on very diverse lines, which on Mendelian principles should not be the case, but Mr. Bunyard considered that such cases lay outside the scope of the Mendelian experiments, which dealt, as far as possible, with known pure forms. Professor Farmer, in conclusion, pointed out the great value of such meetings as bringing together the scientific and the practical men, each being thus able to profit by the knowledge of the other to mutual benefit. A hearty vote of thanks concluded a pleasant and instructive evening.

French Horticultural Society of London.

On Saturday evening last there was a large gathering at the Café Royal, Regent Street, of members and friends of the above society to celebrate the 19th anniversary of its foundation. Mr. Harry J. Veitch occupied the chair, and among the company we noticed M.M. Lageat, Huguenet (editor of "La Chronique"), McKerchar, Ingram, R. Hooper Pearson, Geo. Gordon, Gaskell, J. Weathers, T. Bevan, J. H. Witty, E. F. Hawes, W. Howe, Hiehle, B. Wynne, Such, Ingamells, and others.

The toasts of "The President of the French Republic" and "The King" having been duly honoured with the usual accompaniment of the "Marseillaise" and "God Save the King," the Chairman then rose to propose the toast of the evening. In wishing continued and increasing success to the society, Mr. Veitch said that when invited to occupy the chair he did not hesitate to accept, for two reasons; one was because he was extremely glad to have the opportunity of expressing his sympathy with French horticulture and with La Belle France, the other because he had watched for many years the expansion of this excellent society which had now a membership of 700 on its books. He was proud to think that the young men who came over here thought they could learn something, and he hoped that whatever knowledge they acquired would be profitable. He noticed that they had several grades of members, one of which was a life membership. Although his firm's name appeared on the list, yet his own name did not, and he would take it as an honour if the society would accept him in that capacity. No occupation was so good as gardening, but, like other professions, it was not free from trouble. It had made great progress during the past 50 years, and he could remember many of the most important introductions during that time. He rendered a tribute to the work of the French, mentioning M. Maron, M. Bleu, and M. Lemoine. He also dwelt on the pleasant experience he had in France as a youth, and his indebtedness to the firm of Messrs. Vilmorin, Andrieux, and Co., with whom he stayed. The present generation would have to step into the ranks of the older one, and he hoped they would use their opportunities well. They would have to work if they wished to succeed, but he was not one of those who wished them to do nothing else. Work, however, must come first, and play afterwards.

Mr. Veitch reminded them of the American competition in apples which had flooded the European markets, as a proof of the necessity for exercising their skill in horticulture generally. The society was one that helped them. Through its influence they could form friendships, many of which, and often the best, when formed in youth, lasted a whole lifetime. He reminded them of the success of some of their members, instancing that of their former secretary, M. Louis Gentil, and concluded by saying that, if in future he could assist them or any of their friends, he would always be pleased to do so. He had much pleasure in proposing "Continued and Increasing Success to the Society," and would call upon their worthy president to respond.

Mr. George Schneider, in returning thanks, said that Mr. Veitch's title to their consideration was known to all, and his geniality to their young people was proverbial. He thanked him for his kind words, and he would add that his hospitality in entertaining the society at his residence at East Burnham was not forgotten. Through Mr. Veitch's kindness they had largely been helped in the foundation of the society, therefore it was only right that he should occupy the position he did that evening. The society had received the generous support of the English trade, and he was grateful for their help, for it must not be forgotten that their young men were not rivals. They came here to learn and then go back and help to improve the good fellowship between the horticulturists of both countries. He had much pleasure in drinking to the success of English horticulture.

Mr. J. McKerchar followed with a humorous speech. He hoped that in future all rivalry between the two countries would be confined to the friendly rivalry in horticulture, and that by closer intercourse the two peoples would know each other better. The society had been assisted in the past by the help of former chairmen, to whose health he would ask them to drink.

On behalf of past chairmen Mr. Harman Payne replied, referring briefly to the death of Mr. Arnold Moss, and to the enforced absence of M. Philippe de Vilmorin. The society had been helped largely by the officers, one of whom—M. Ripard—had very kindly decorated the tables with great taste, and to whom their thanks were due. Mr. Ripard briefly replied, expressing the society's obligations to the horticultural Press for much valuable assistance. To this toast Mr. George Gordon returned thanks.

Other toasts were "The Chairman," proposed by M. Lageat, and "The French Press," proposed by the Chairman, and responded to by M. Huguenet, of "La Chronique."

There was an excellent musical programme, and the whole proceedings were of the most enjoyable character.

The Linnean Society.

THE CABBAGE FAMILY.

In various places on our sea coasts the wild cabbage grows in the form of a somewhat fleshy-leaved weed with small yellow cross-shaped flowers, and no one, looking at it, would imagine that such a plant could be the origin of the wonderful wealth of nutritious vegetables which we possess in the shape of cabbages of various forms, shapes, and colours, kales of equal variety, cauliflowers, broccoli, Brussels sprouts, and even that singular turnip-like form, kohl rabi. It is, however, beyond all doubt that it is to the peculiarly sportive nature of this weed, and its singular capacity of responding to high culture, that all these varieties are due. Our seedsmen's catalogues will also show us that each of these types has given innumerable sub-varieties, so that there are hundreds of varied descriptions.

The process of selection which has led up to these is, however, still going on, and Mr. Arthur W. Sutton, F.L.S., of the well-known Reading firm, gave a most interesting paper at the Linnean Society on Thursday, the 16th instant, which, being illustrated by a large number of lantern slides, showed how even this multitude of forms could be increased by crossing, several new ones of great value being exhibited, such as combinations of Brussels sprouts with the savoy and other cabbages, increasing size and weight, and consequent food value. Independently, however, of such acquisitions, the experiments described by Mr. Sutton had for their object the settlement of the vexed question among seed growers as to how far plants of these different forms, grown for seed, could be safely associated without risk of deterioration by intercrossing, a risk which has on more than one occasion led to lawsuits, seed supplied having mysteriously yielded inferior or even worthless crops, although derived from apparently reliable sources. In this connection it is not merely the cabbage species proper (Brassica oleracea) which is concerned, but its near allies, the turnip, the swede, and the rape, which, as Mr. Sutton's slides clearly demonstrated, are capable of intercrossing to some extent, a possible result being that a crop of turnip seed may be so affected by neighbouring rape pollen that few or no turnips would result, the rape influence predominating.

The paper had also considerable interest from the purely scientific side, and a number of prominent scientists were consequently present to hear what evidence the experiments afforded in connection with the Mendelian theory, or rather, law, of inheritance of characters, and it was noted with great satisfaction that, although the families concerned were of such a variable nature, the ratios in which the two parental characters of crossed forms came out separately and clearly in the next generation but one, agreed closely with what that law would lead us to expect. Returning to the question of purity of seed crops, it was clearly established that certain varieties and species might quite safely be grown side by side, or even intermixed, without the least risk of crossing; while others crossed so freely under like circumstances that a more or less impure and mongrel crop of plants was sure to result from their seed. The long series of experiments concerned had therefore had a threefold value, by giving us new and improved vegetables for culinary purposes, instructing seed growers as to what crops might or might not be grown in association, and finally by adding some important data to our scientific knowledge of the laws underlying inheritance which, until Mendel's theory was published, remained an apparently insoluble enigma.

Professors Farmer and Percival, and Mr. Bateson, in the subsequent discussion, emphasised the value of Mr. Sutton's experiments, especially from the scientific point of view. The additional paper on the tuber-bearing solanums was unavoidably postponed owing to lack of adequate time.

Weybridge Horticultural Society.

The January monthly meeting of this horticultural society was held onTuesday evening last, the president, J. Lyle, Esq., presiding. Over fifty members were present. Mr. Goatley, of Sutton Place Gardens, Guildford, gave an instructive lecture on "The Cultivation of Calceolarias and Cyclamens." Many useful hints were given by the lecturer, and they should prove valuable to the members present.

Well-grown amaryllis, primulas, freesias, and Brussels sprouts were staged by members, and a discussion on the lecture and exhibits closed a successful opening meeting for the year.

London Dahlia Union.

The annual meeting of this body was held at the Horticultural Club, Hotel Windsor, Victoria Street, S.W., on January 16, when Mr. John Green presided. There was a fair attendance, and most of the leading dahlia growers were present.

After the preliminary proceedings the report and financial statement were presented as follows:—

COMMITTEE'S REPORT FOR 1907.

Though only constituted as a society in 1904, your committee are gratified to find that the interest in the dahlia is fully maintained, and to report that the year's working has been of a most satisfactory nature.

The annual exhibition was again held in the Gardens of the Royal Botanic Society, at Regent's Park, by kind permission of the Council, to whom the best thanks of the members are due. It was generally acknowledged by all who visited it that the show was the finest yet held under the auspices of the union. The best thanks of the members are therefore due to the exhibitors who so readily came forward and assisted in forming so grand a display.

Your committee are also pleased to find that the membership is steadily increasing, and desire to ask all members of the union to introduce at least one new subscriber during the year.

It is also satisfactory to note that at the end of the year's working the union has a balance of assets over liabilities, amounting to £11 6s. 8d., and this after carrying on a bolder propaganda for bringing the work of the union before the notice of the dahlia-loving world than previously.

Your committee are at present unable to state definitely the place and date of the exhibition for 1908, as they are negotiating with the various authorities, but they hope to decide the matter as early as possible.

The best thanks of the union are also due to the Press, and other kind friends who so ably assisted at the exhibition, to the donors of special prizes for their continued support, and also to the Horticultural Club for allowing the use of their rooms for the meetings.

FINANCIAL STATEMENT 1907.

RECEIPTS.

	£	s.	d.
To Balance Brought Forward	23	8	6
Annual Subscriptions, 1907	34	2	6
Special Prizes, 1907	7	9	6

Dean Memorial Dies, less 25 per cent.	4	16	0
	£37	6	8

These were adopted without dissent.

Mr. John Green was re-elected president; Mr. E. F. Hawes was re-elected secretary; Mr. R. Ballantine was re-elected auditor; and the four retiring members of committee were also re-elected, and in every case the election was unanimous and accompanied by hearty thanks for services rendered. A few slight alterations of rules necessary to keep pace with the times were made.

It was agreed that the Dean Memorial medals should be awarded to pompon dahlias in 1908. Mr. J. Green observed that he proposed to conduct an extensive trial of garden cactus dahlias at Dereham during 1908, and he suggested that three members be elected to visit these trials, and make awards in conjunction with representatives from the National Dahlia Society, etc. The matter was left in the hands of the committee, as also was the revision of the schedule.

A vote of thanks to the president concluded the proceedings.

British Gardeners' Association.

At the last meeting, Mr. C. Foster in the chair, ten new members were elected, bringing the total up to 1,138. A keen discussion took place as to turning the quarterly "Journal" of the association into a monthly publication. It was eventually decided in favour of a "monthly" after the next quarterly issue, which would complete the year, and subject to full details as to cost, etc., to be submitted at the next meeting.

A resolution in favour of legislation in Parliament for the establishment of old age pensions was carried, and Messrs. Lewis and Little were appointed a sub-committee to watch the procedure and report any progress made. A sub-committee was also appointed to prepare a practicable scheme for the examination of gardeners, the details to be ready by the annual meeting.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, January 14.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair); Dr. Farmer, Messrs. G. Nicholson, C. T. Druery, E. M. Holmes, J. Douglas, H. T. Güssow, W. Cuthbertson, G. Gordon, C. H. Hooper, W. C. Worsdell, G. Saunders, and F. J. Chittenden (hon. sec.)

WEEVILS ON GREASEBANDS. — Mr. Saunders reported that the three weevils captured on the greasebands shown at the last meeting belonged to a species of Magdalinus, but they were too much battered to make out the exact species. There appears to be no record of them attacking plants to a serious extent.

MALFORMED FLOWER OF DENDROBIUM NOBILE.—Mr. Worsdell reported that he had examined the very curious malformed flower of Dendrobium nobile sent from the R.H.S. Gardens to the last meeting. He found an attempt at the making of a dimerous flower, but the attempt was partially abortive. Two sepals only were developed, and two petals, one lateral, the other half of the form and colour of the labellum, and half of the form and colour of an ordinary petal. The latter petal was inserted partly in the position usually occupied by the labellum, and partly in the position normally occupied by one of the other petals. The ovary had aborted.

ORNITHOGALUM LACTEUM.—Mr. E. M. Holmes showed a flowering specimen of this plant sent from the Cape. The bulb had not been planted, nor, apparently, supplied with moisture.

FASCIATED HOLLY.—Dr. Farmer showed a curiously fasciated and twisted specimen of the common holly. The stem was fully an inch in breadth, and curled round at the apex.

COLOUR AND SCENT OF FLOWERS.—Mr. Douglas raised the question as to whether there was any relation between the colour and scent of flowers, remarking that there certainly seemed to be in the case of carnations. The subject would apparently repay investigation.

INOCULATION OF LEGUMINOUS PLANTS.—Mr. Chittenden produced a copy of the suggested plan for carrying out a trial of the effect of inoculating peas with cultures of nodule forming bacteria at Wisley, and explained the manner in which it was intended to estimate the result, etc.

DISEASED PLANTS.—Several specimens of diseased plants were received and dealt with.

Chorlton-cum-Hardy Amateur Gardeners' Society.

At the first annual meeting of this society Mr. Woodall presided. There was a large attendance, and the Chairman remarked that it was with very great delight he looked back upon what this society had done during its year of existence. They could boast of a membership of 250, and officers who had performed their duties to the utmost satisfaction of all. They had formed a library, with about 40 books. They had had two outings during the summer, one to Earl Egerton's Gardens at Tatton Park, Knutsford, and the other to Mr. Bell's (Mayor of Stockport) Gardens. They had also held a summer show in August, when 200 entries were received. The lectures and social evenings had been instructive and enjoyable, and they had also been the means of starting another society called the "Didsbury and District Amateurs' Society."

Mr. Woodall then went on to say that the Chorlton Society had a very bright future before it, and he hoped the gentlemen elected for the different offices would carry on the work efficiently.

The Secretary (Mr. W. Scott) said the society was doing its utmost at the present time to acquire a piece of ground suitable for about fifty allotments, and he hoped to be able to report a settlement in a few weeks. The dates had been fixed for three shows for 1908—a rose show on July 18; a summer show on August 22; and an autumn show on November 14.

The Treasurer (Mr. J. Carroll) reported an income of £58 10s.; expenditure, £49 2s.; and balance in hand, £9 8s.

A hearty vote of thanks was accorded to all the retiring officers, and these were re-elected, and six new ones added.

GARDENING AND GARDENERS.

The article by "A. G. B." on "Recognition of Gardeners" in your issue for December 28 is interesting to all who have the best interests of the profession at heart; but I much question whether the remedies he proposes will prove to be the panacea for all the ills under which the gardener labours, and while I shall be the last to raise my voice against examinations in practical horticulture, or any other subjects that will tend to his improvement and fit him for a position of trust and responsibility, I question whether "A. G. B." is not making a grievous mistake when he supposes that such will have the effect of lifting the profession, and those who follow it, on to a higher plane in the world's estimation.

But before pursuing this line of thought further, and with the article in question before me, I am bound to ask—is the gardener that lowly and much-despised creature which seems to be suggested? I think not. I have moved about the country, and have invariably found that men holding respectable and responsible positions as gardeners, whether in private, public, or business establishments, are looked upon as men of intelligence and respectable social position; and surely the standard of excellence to which gardening has been raised and is found to-day has been brought about very largely by these, whom your correspondent appears to very much underestimate because, maybe, some of them lack that scholarly ability which we are asked to believe is going to revolutionise the profession.

Please do not misunderstand me. I do not underestimate the importance of education, but one cannot shut their eyes to facts; these very men who have done so much for British gardening have been trained in the severe, but best of all schools—practical gardening; and while "A. G. B.'s" remarks about the grading of gardeners by the B. G. A. as apprentices and under gardeners, may be all very well for those entering upon their life's work, and who have chosen gardening as their profession, I ask—where will he place those to whom I refer? Will he, because they are unable to give answers to questions in horticulture set in examination papers, in the form of highly finished written papers, but who are, nevertheless, thoroughly practical in their profession, pass them by as amongst the "unfit"? Or what provision does he propose for them whereby they may become possessors of this much-prized certificate? Surely there is a way out of the difficulty, if it be so very necessary to obtain it?

My suggestion is to hold an examination under the auspices of the R.H.S., in practical gardening, in two parts, viz., "viva voce" and "practice." Subject these men to answering questions orally, and then subject them to practical tests, as seen in their manner of procedure to carry out certain work requiring skill and practice, and methinks many of them will "romp home" easy firsts, and with honours, whilst those who may have made progress in the written work by reason of some scholarly ability and cramming will find great difficulty in reaching home at all.

With regard to the step taken by the L.C.C. with reference to certificates, it is good in so far as it goes in acting as a stimulus to the young men to read up subjects bearing upon horticulture and become more observant in their work, and to improve their general education; but this is exactly where my suggestion seems to me to be of most effect, as there are, no doubt, many men who are amongst the best of the Council's gardeners, capable, trustworthy men, but lacking in that general education which would enable him to take a certificate in a written examination, but none the less men of intelligence, and we do them great wrong if we make no provision for them.

"A. G. B.'s" suggestion to our leading nurserymen, I am afraid, will fall upon deaf ears. What the nurseryman requires, and always insists upon (and I trust always will) is the man who is thoroughly practical, and what he invariably asks is not "What certificates do you hold?" but, "Where have you received your training which fits you to hold the position for which you offer yourself?" And just in proportion to the training the applicant has received does the nurseryman form his opinion of the man's fitness; and while there is much to be said in favour of certificates, no one can deny this is the safer method to adopt. For this reason I much prefer the old-fashioned idea of apprenticeship, where the lad starting on his life's work has to serve a term of years and at the expiration of the period arranged, which may be four or five years, receives his indentures or a testimonial to the effect that he has been trained in practical horticulture, to the one whereby many doubtlessly are "pitchforked" into the gardening world (as "A. G. B." remarks), and are, by reason of a fair education and reading up gardening subjects, able to take the certificate; but many of whom in practice would be more or less failures, for the simple reason that they have drifted into the profession without any serious attempt to become proficient in it. These latter are not the men our nurserymen are looking for, neither are they those who are calculated to materially alter the status of the gardener.

Depend upon it this social improvement will come just in proportion to the number of lads of high moral character who enter the profession with a fixed determination to master it, and make themselves respected in the world, not only for their knowledge of gardening (which is most important), but by the loftiness of their character and the influence for good they bring to bear upon those around them. In this way will the profession be lifted higher by each individual effort; and it is here that the crux of the matter lies in so far as the rising generation is concerned; we want it made attractive to this class of youth. The difficulty is how to do it. In so far as moral tone is concerned depend upon it we who are now in the profession may do much in this way. "Like begets like." Let us not forget that old proverb. Lads of high principle will to a certain degree be attracted as we do our part; but there must be more, it must be made more lucrative. Ah! there's the difficulty, but depend upon it that is the key to the situation. And good as certificates may be I do not believe they are going to make that difference which "A. G. B." suggests.

Surely "A. G. B." does not mean that the labourer is incapable of the same high moral character as the gardener? If so, I strongly resent such an idea: for this great highway is peopled by no particular class; the king and the peasant have equal rights and opportunities to tread its well-worn paths, and many of those found there are the humble labourers. Again, surely "A. G. B." is forgetting the high esteem in which many garden labourers are held by their employers, who, whilst recognising in the gardener a man whose calling and training has made more intelligent, and who respect him very highly as such, still fail to see any great gulf between the two in moral character. And surely your true garden labourer is a skilled labourer in the true sense of the word, for there is a wide difference between him and the class of worker we call the "general labourer." And so I would urge that, whilst anxious to improve the status of the gardener, we should be careful lest we place ourselves in the position of the Pharisee. L. B.

Dulwich.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

RHODODENDRONS.—S. N. C., Devon: Your question will be answered in our next issue.

PÆONY - FLOWERED DAHLIAS. — D. W. C. R., St. Paul, Minn.: We believe the raisers, or at least the original introducers of pæony-flowered dahlias were the Messrs. Copijn, of Groenekan, near Utrecht, Holland.

SCARLET SALVIAS.—B. C., Leamington: Cut back the old plants at once, and place them in a warmer house, near the glass. Here they will soon commence to grow, and as soon as these new growths are large enough they should be taken off and inserted as cuttings in sandy soil.

YORKSHIRE GALA.—S. M., Sandy: The secretary of the Yorkshire Gala Committee is Mr. Fred Arey, Davyhill Chambers, Davygate, York. You should procure a copy of the "Gardening Year Book" for 1908 (1s. 2d. post free, from Messrs. W. H. and L. Collingridge, 148 and 149, Aldersgate Street, E.C.), as it contains a complete list of horticultural societies, with name and address of secretary in every case. It is a useful book in other respects, and very handy for the desk.

FAILURE WITH CHERRY TREES.—J. W. W.: Provided the trees were carefully planted we fail to understand why so large a percentage have failed altogether. Too often trees are not properly cared for when received from the nurseryman; when unpacked they should be at once laid in in moist soil, and if they appear dry they should first of all be immersed in water for a few hours. The great majority of early failures must be attributed to carelessness in this respect or in planting. We assume you staked the young trees, but you tell us so little we can only guess at the cause. Perhaps you can supply us with further information.

PEAT MOSS v. STRAW LITTER. — M. E. G., Devon: Two years ago experiments were conducted at Wye Agricultural College for the purpose of discovering the relative merits of peat moss litter manure and straw litter manure. Considered only for their fertilising matter, analyses showed the following results:—

	Peat Moss.		Straw.
Nitrogen	.83	...	.45
Phosphoric Acid	.10	...	.32
Potash	.17	...	1.64

Ignoring the mechanical effect altogether, it will be seen that peat moss litter is far richer in nitrogen than straw litter, and poorer in potash and phosphoric acid. But it must be remembered that potassic and phosphatic fertilisers can be purchased more cheaply than nitrogenous ones.

POTTING LÆLIA ANCEPS.—S. J. B., Sevenoaks: It is too early yet to pot Lælia anceps. This orchid needs a fairly long season of rest after it has flowered, longer, perhaps, than any other orchid needs. After flowering it should be kept at the coolest end of the house, and given little or no water for some time to come. Late in the spring new growths will begin to appear, and new roots quickly follow; this is the proper time to pot or repot Lælia anceps. You do not say in what condition your plant is, therefore we are unable to advise you whether it should or should not be potted. It is surprising how little root room this orchid needs and how long a plant will remain in good condition in a quite small receptacle suspended from the roof.

AGRICULTURAL SCHOOL IN HAMPSHIRE.—F. E. C., I. of W.: You had better apply to Mr. J. C. Newsham at the Hampshire School Farm, Basing. At this school provision is made for training lads or young men in winter and women in summer. The winter course lasts for twenty-four weeks and is thoroughly practical. Indoor instruction for about one hour is given each morning and afternoon. As regards outdoor work, the lads are divided into four groups, each taking a month at farm work, in the dairy, with the poultry, and in the garden. Once a week they are taken to Basingstoke market. The summer course is designed mainly for women, and is divided into three periods of five weeks each. It is largely devoted to dairying. The fees for pupils from Hampshire are 10s. per week for those connected with dairy work or farming, and 15s. for other Hampshire pupils, including board, lodging, and tuition. All other pupils, £1 5s. per week. The farm consists of 71 acres, 31 acres being dry pasture, 15 acres water meadow, and the remainder arable. There is also a specially built dairy and a garden of about one and a-half acres.

ROSES.—E. T., Walsall: Carefully remove the loose surface soil, and then cover the whole area of the rose bed with half-decayed manure, making this firm with the back of the fork and covering it with some of the surface soil removed. The manure should be rich, but not wet or rank; decayed cow manure that is readily workable, is good material, especially for light soils. A good artificial dressing to be applied in early spring and hoed or forked in and also watered in, consists of 12lb. of superphosphate of lime, 10lb. of kainit, and 1lb. of sulphate of iron, all well mixed together, and then used at the rate of ½lb. of the mixture to each square yard. In May and June, if the weather be at all dry, and the soil at all light, it is a good plan to dissolve a quarter ounce each of sulphate of ammonia and nitrate of soda in two gallons of water, and give this quantity to each rose tree or bush once every week or ten days. Clear soot water is also an excellent stimulant and fine for syringing the leafage to keep insect pests at bay, but it must be very carefully used when roses are expanding, or, clear as it may be, it will leave marks on the delicately-hued petals.

THE ART OF STOKING.

A correspondent by no means unknown to our readers contributes the following note, among other gardening items, to the "Estate Magazine":—

Very great advances have been made in the heating of glass houses since the old days of brick flues, and much credit is due to hot-water engineers for the introduction of various makes of boilers which heat quickly and with a minimum amount of fuel. It is part of the professional gardener's business to learn how to stoke and know something of the principles which govern the circulation of hot water. Stoking, in fact, is one of the first lessons that a gardener has to learn, and many of mature age doubtless remember the time when they marched from fire to fire on wintry nights banking up, or turned out in the small hours of the morning when the thermometer registered many degrees of frost to start the fires going and get the heat up. This is the only way to learn stoking, and, assuming that all professional readers have acquired the knowledge in the school of practice, I will direct my remarks to members of the amateur fraternity who become possessors of conservatories and greenhouses, and have to undertake the responsibilities of heating them.

The amateur, by the way, who has aspired to the possession of a small greenhouse, often finds that his troubles have begun when the winter comes along, and he has to adopt artificial means of heating, because it is much more difficult to regulate the temperature in a small structure than a large one. The length of piping is short, the quantity of water to be heated small, and if great care is not taken in the manipulation of dampers the fire rattles away and the water is heated to boiling point, which means emptying of pipes and a lot of additional trouble. When the pipes are heated so much that it is hardly possible to bear the hand on them, the house gets suffocatingly warm, and if the boiling should take place in the night, when no one is at hand to give attention, the chances are that the house may be quite cold by morning. This is the amateur's trouble with his heating arrangement, the house is either too hot or stone cold, and either extreme is bad for plants. Fortunately, however, boiler-makers have realised these difficulties, and have overcome them to some extent by introducing boilers of sufficient capacity to heat small houses, and the fire can be regulated so that it will burn slowly and maintain a steady heat. A boiler, like a motor-car, wants understanding, and, having become accustomed to whatever kind of apparatus is used, the thing is to attend to cleanliness and detail. "Keep your bars clear" was the advice given to me years ago by an old gardener, and I have proved the value of it scores of times. A whole furnace full of fire will not heat the pipes if the bars are choked with dust and ashes, but if the latter are clear, and there is a good draught, a small handful of fuel will suffice. Before banking up a fire for the night it should be well cleared of clinkers and cinders, and a few ashes put on the top of the fuel are a means of economising the same. A little experimenting with the dampers puts one in the position of knowing how long the fire may be expected to last and keep up a gentle heat, and when one has acquired this knowledge the principal difficulties of heating a small house are overcome. As I said before, the chief thing is to avoid extremes of heat and cold.

OBITUARY.

◆

MR. J. R. PETCH.

At the advanced age of 71 years Mr. J. R. Petch passed away on Sunday, January 12, at St. Peter's Hospital, Covent Garden, after undergoing an operation. The deceased was very widely known among horticulturists, as he was formerly a traveller for Messrs. Richard Smith and Co., of Worcester, and latterly for Mr. L. R. Russell, of Richmond. Mr. Petch was at one time in business for himself as a florist and seedsman, at Saffron Walden, but gardeners of the elder generation will remember him as head gardener to Samuel Mendel, Esq., at Manley Hall, Manchester. He was a splendid cultivator, knew plants well, and had a fine collection under his charge. It will be remembered that one of the most beautiful of cattleyas (C. Mendeli) was named after his employer. Mr. Mendel was a successful cotton merchant, and he gave Mr. Petch some cotton seeds to experiment with, the result being that to Mr. Petch must be accorded the honour of first cultivating cotton successfully in this country. The cotton he produced was spun into yarn by a hand loom weaver engaged by another celebrated horticulturist—the late Mr. Samuel Barlow, and some handkerchiefs were made and presented to Mr. Mendel on his birthday. This little episode created a good deal of interest at that time.

THE GARDENERS' MAGAZINE.

NOTES OF THE WEEK.

The Nickerson Prizes for Roses.

It will be remembered by those who take an active interest in roses that last year Mr. W. E. Nickerson, an enthusiastic rosarian resident at Boston, U.S.A., presented three silver cups to the National Rose Society, to be awarded to the raisers of the best hybrid perpetual, the best hybrid tea, and the best tea-scented variety introduced within a prescribed period. The award of these cups was entrusted to a specially appointed committee, and in the result the raisers of Frau Karl Druschki, Madame Jules Gravereaux, and Dean Hole, were adjudged the winners. As these roses are of German, French, and Irish origin no one could well suggest that in the making of their awards the members of the committee were influenced by insular prejudice. Their selection has been questioned by some, but this has been largely due to the fact that the time limit has been overlooked. Mr. Nickerson was so well satisfied with the results that this year he has placed twelve cups at the disposal of the society for honouring the best dwarf and climbing roses, without any stipulation as to the year of introduction. He suggests that four cups should be awarded for bush roses, four for climbers blooming in trusses, and four for climbers with flowers not in trusses, the cups in each group to be awarded to the best red, the best pink, the best white, and the best yellow variety. All colours are to be admissible and to be arranged under the head to which they approach most nearly. For example, all reddish shades deeper than deep pink are to be classed as red; salmony, etc., shades to be classed as pink; canary, buff, orange, etc., shades to be classed as yellow, and all very light tints or shadings to go with the whites. These suggestions are of much value, and will, we have no doubt, be acted upon, but it is not difficult to foresee that the preparation of a scheme for giving practical effect to Mr. Nickerson's views will require much care and thought; and this we know will be ungrudgingly given by the executive of the National Rose Society. The climbers flowering in trusses are such varieties as Crimson Rambler, Dorothy Perkins, and Lady Gay; and the climbers producing their flowers singly or at most a few in a cluster are best represented by Aimée Vibert, Gloire de Dijon, and Madame Berard. Believing that the only method by which anyone can obtain a really complete and accurate idea of the value of a variety, Mr. Nickerson recommends that the lists sent to those taking part in the election should contain a scheme of marking by points. For example, one hundred points would constitute a perfect variety, one in which the flower is faultless in form, colour, opening, keeping qualities, fragrance, etc.; the foliage, growth, hardiness, resistance to blight and pests of the highest order, while the plant should bloom continuously. It is suggested that each of the following qualities should be covered by five points each, and in putting this into practice on Frau Karl Druschki, Mr. Nickerson obtained the following result: The flower—Form, 3; size, 4; substance, 4; colour, 5; permanence of colour, 5; distinctiveness, 4; flower stem, 4; fragrance, 0; opening, 4; keeping, 3; total, 36. The bush—manner of growth, 3; vigour of growth, 4; constitution and healthiness, 4; adaptability to situation, 4; colour and brightness of foliage, 3; form and arrangement of foliage, 3; hardiness to cold, 4; resistence to mildew, 3; freedom of bloom, 3; continuity of bloom, 3; total, 34; or a grand total of 70. It is believed that if some such plan as is here briefly explained could be adopted and clearly set forth in the circular letter accompanying the voting list, much useful information would be brought out about the qualities of the roses voted upon as they appear from different points of view, and in different localities. On the other hand, it is feared that without a point-marking scheme many taking part in the election will vote without the proper amount of detailed and definite thought, giving mere impressions which they may have, and in any case it would not be known on what grounds their opinions were based. Recognising the fact that under the scheme only twelve roses will be honoured out of the scores entitled to distinction, Mr. Nickerson very generously offers to place a sum of money at the disposal of the National Rose Society for the purpose of having a suitable diploma prepared, so that the second and third most popular roses in each section may receive proper recognition. In addition he suggests that all roses receiving a certain percentage of the votes be named in the published account of the contest, it being thought that in this way probably the most popular hundred roses or thereabouts will become known to the rose world as such. Mr. Nickerson's suggestions for ascertaining which are the most popular roses are so new in character and comprehensive in scope that the election can hardly fail to prove of immense interest to rosarians, and the results of much value to all who grow roses. The preparation of the scheme, and the carrying out of the details will be not the least important of the work included in

MR. H. BALLANTINE, V.M.H.

the programme of the National Rose Society for the current year, and the display of the winning varieties will, unless we are much mistaken, be not the least attractive of the many features of its metropolitan exhibition in July next.

Mr. H. Ballantine, V.M.H., whose portrait we have the pleasure of giving herewith, is one of the best known of gardeners, and is held in high esteem both for his great cultural skill and geniality of disposition. Exactly how many years Mr. Ballantine has had charge of the gardens of The Dell, the charming residence of Sir Henry Schroder, Bart., at Englefield Green, we are not now able to say. We are, however, able to state that he has occupied his position for a very long time, and that throughout the period the gardens have been regarded, and properly so, one of the most noteworthy horticultural establishments in the country. The Dell gardens have become the most famous for their collection of orchids, and having regard to the extent of the collection, the great value of large numbers of the varietal forms, and the splendid development of many of the specimens, this is in no way surprising. The collection of orchids is unique, but the gardens contain many features, each one of which is sufficient to make them famous. The collection of choice rhododendrons is extensive, and the condition of the plants such as to evince cultural skill of the highest class, while the rock garden with its many beautiful alpines presents many charms to lovers of hardy flowers. Mr. Ballantine possesses in an eminent degree the skill and judgment essential to an orchidist of the highest class, but he is equally at home in all other departments of the garden, as proved to demonstration by the splendid results that are annually obtained. Last year Mr. Ballantine had the well-deserved honour of receiving from the Council of the Royal Horticultural Society the Victoria Medal of Honour in Horticulture.

Gardens Around Horsham.—We would remind our readers that in the issues of the GARDENERS' MAGAZINE for the 8th and 15th inst. we shall describe and illustrate some of the most notable gardens in the district of which the town of Horsham is the centre. This is one of the most important gardening centres in Sussex, both as regards the number of important gardens and the great interest that is associated with them. Both issues will be profusely illustrated with finely executed reproductions of photographs specially taken for the purpose.

New Flowers at Vincent Square.—We learn with very great pleasure that on and after February 11, all plants and flowers to which a first-class certificate or award of merit are granted by the Floral Committee of the Royal Horticultural Society must be staged on a table in front of one of the annexes in the hall, instead of being returned to a group that the exhibitor may have arranged. As a rule, after the committee rises, the certificated plants become distributed through the exhibition and are therefore most difficult to find. We have on previous occasions urged that all new plants and flowers receiving official recognition should be set up in a special position together, because of the greater convenience such an arrangement offers to the general public, and because such a proceeding is in accordance with the original intention of the fortnightly meetings. We hope the other committees will follow the example of the Floral Committee in this matter.

The Chester Paxton Society's programme for the second half of the winter session commenced on January 18 with a lecture by Mr. J. W. Siddall on "Springtime in the Undercliff District of the Isle of Wight." The other lectures are on February 1, "The Common House Fly," by Mr. R. Newstead, A.L.S.; February 15, "The Flora of India and Ceylon," by Mr. Joseph Thompson; and February 29, "Herbaceous and Alpine Plants," by Mr. W. S. Sharp.

Brassica Hybrids.—At the meeting of the Scientific Committee of the Royal Horticultural Society on Tuesday an important paper was read by Mr. Arthur Sutton, V.M.H., on Brassica hybrids. The meeting was on this occasion held in the lecture room, which was well filled. The comprehensive experiments on which Mr. Sutton's paper was based were commenced in 1905, and were conducted with a view to determine the extent to which the several kinds will intercross. In the course of the experiments it was proved to demonstration that the brassicas which had originated from the wild cabbage readily intercrossed with each other, but would not enter into union with the rapes, turnips, or kohl rabi. As the result of the intercrossing of the descendants of the wild cabbage, two distinct forms of much value for culinary purposes was obtained. One of these was derived from a cross between the Brussels sprout and the savoy, and the other originated from a cross between the Brussels sprout and an ordinary cabbage. Numerous hybrids were obtained between the rape and the thousand-headed kale, but these were for the most part sterile. Hybrids were also obtained between the thousand-headed kale and kohl rabi, and between the kale known as Ragged Jack and the swedes. The first year the progeny was of a very mongrel character, as might, Mr. Sutton said, have been expected, but in the following season the plants raised from seed saved from the hybrids resembled, in well-defined proportions, the forms used in making the original crosses. There was a brief but interesting discussion, and in the course thereof Mr. Sutton, in answer to an inquiry, expressed the opinion that it would probably not be possible to bring the hybrids obtained to the same high degree of perfection as the parents within the course of an average lifetime.

Preservation of Ludshott Common.—An appeal is being made by the Ludshott Common Preservation Committee for the funds necessary for the purchase of Ludshott Common, which forms one of the group of commons at Hindhead and the tract of woodland between the common and Waggoner Wells. The 542 acres of common, and the 17½ acres of woodland can be purchased for £1,675, and the legal and other expenses are estimated at £125. Towards the £1,800 thus required £700 has already been subscribed. It is proposed if the purchase is effected to vest the land in the National Trust for places of Natural Beauty. Mrs. Lyndon, of Grayshott, is the honorary secretary of the committee.

R.H.S. Guild.—The movement on foot for the promotion of a guild of old Chiswick students and officers, and old and present Wisley employees of the Royal Horticultural Society is receiving the attention it merits. To put the whole matter on a definite basis and to decide the title, rules, etc., a meeting of those eligible to join the guild will be held in No. 3 Committee Room, at the Royal Horticultural Hall, Vincent Square, Westminster, on Tuesday, February 11, at the conclusion of the R.H.S. annual meeting. It is hoped that all old Chiswick and Wisley men will do their best to attend.

Field Botany Excursion.—An interesting experiment in field botany has been conducted for three successive seasons by Prof. F. W. Oliver, F.R.S., of London University College. A large area of salt marsh at Erquy, in Brittany, was selected, and this it was proposed to inspect for many successive years for the purpose of noting the distribution of plants, migration, differences of plants in varying degrees of salinity of soil, alteration of conditions and plants, and other similar and useful questions. Upwards of twenty students have joined each year in this most interesting study, and they have spent a most enjoyable as well as profitable time at Erquy.

Fall of a Giant Poplar.—During the December gales a very noble specimen of Populus deltoides was blown down in Christ Church Meadows, Oxford, a few yards west of the Oxford Botanic Garden. This tree had attracted the attention of many persons interested in aboriculture. When divested of lop and top its trunk measured 55 feet in length; girth, twelve feet from base, 16 feet; it contained 1,056 cubic feet of timber, and weighed 20 tons. Last year G. Claridge Druce, Esq., collected leaves of it for distribution to the members of the Botanical Exchange Club of the British Isles, in order to contrast it with the foliage of another giant black poplar growing close by. The specimen under note had very large clusters of mistletoe, supposed to have been brought by the birds from the Botanic Garden, where there is a large display of this parasite. This form of poplar grows rapidly in the Midlands, and though its wood is soft it is tough. To remove the tree, which fell across the west arm of the river Cherwell, was a task of considerable difficulty, for chains and steel cables attached to it snapped like cotton under the strain of a powerful Burrell compound engine. However, after two days' work the log began to roll, it was drawn ashore, cut in half, and conveyed to Littlemore, three miles distant.

Rose Culture at Bristol.—Under the auspices of the St. Martin's Branch of the Church of England Men's Society, a series of lectures has been arranged for the winter session. The January lecture, given in the schoolroom by Mr. T. P. Elkes, head gardener at St. Agnes' Home, Knowle, Bristol, deserved a larger audience than it received. The subject, "Roses and their Culture," was ably dealt with by the lecturer, who, dealing first with the historical side of the national flower, led his audience by easy stages through the different phases of successful rose culture, illustrating his remarks on pruning by practical demonstrations on varieties he had specially selected and potted for the purpose.

The Horticultural Club Annual Dinner will take place on Tuesday, February 11, at 6 p.m., at the Hotel Windsor, Victoria Street, Westminster. After dinner there will be music under the direction of Mr. F. Morrison. Those desirous of attending this function, to which ladies are especially invited, should notify the Secretary, Mr. E. T. Cook, not later than February 16, as accommodation is limited.

Scottish Horticultural Association.—The Right Hon. Lord Elphinstone has been elected hon. president of this association for 1908; Mr. James Whytock is president; Messrs. D. Kidd, W. H. Massie, and M. Todd, vice-presidents; and Mr. A. D. Richardson, secretary and treasurer. The retiring president, Mr. D. W. Thomson, was presented on January 4 with a finely illuminated address in appreciation of his services to the association whose membership is now 1,306.

STANDARD ROSES.

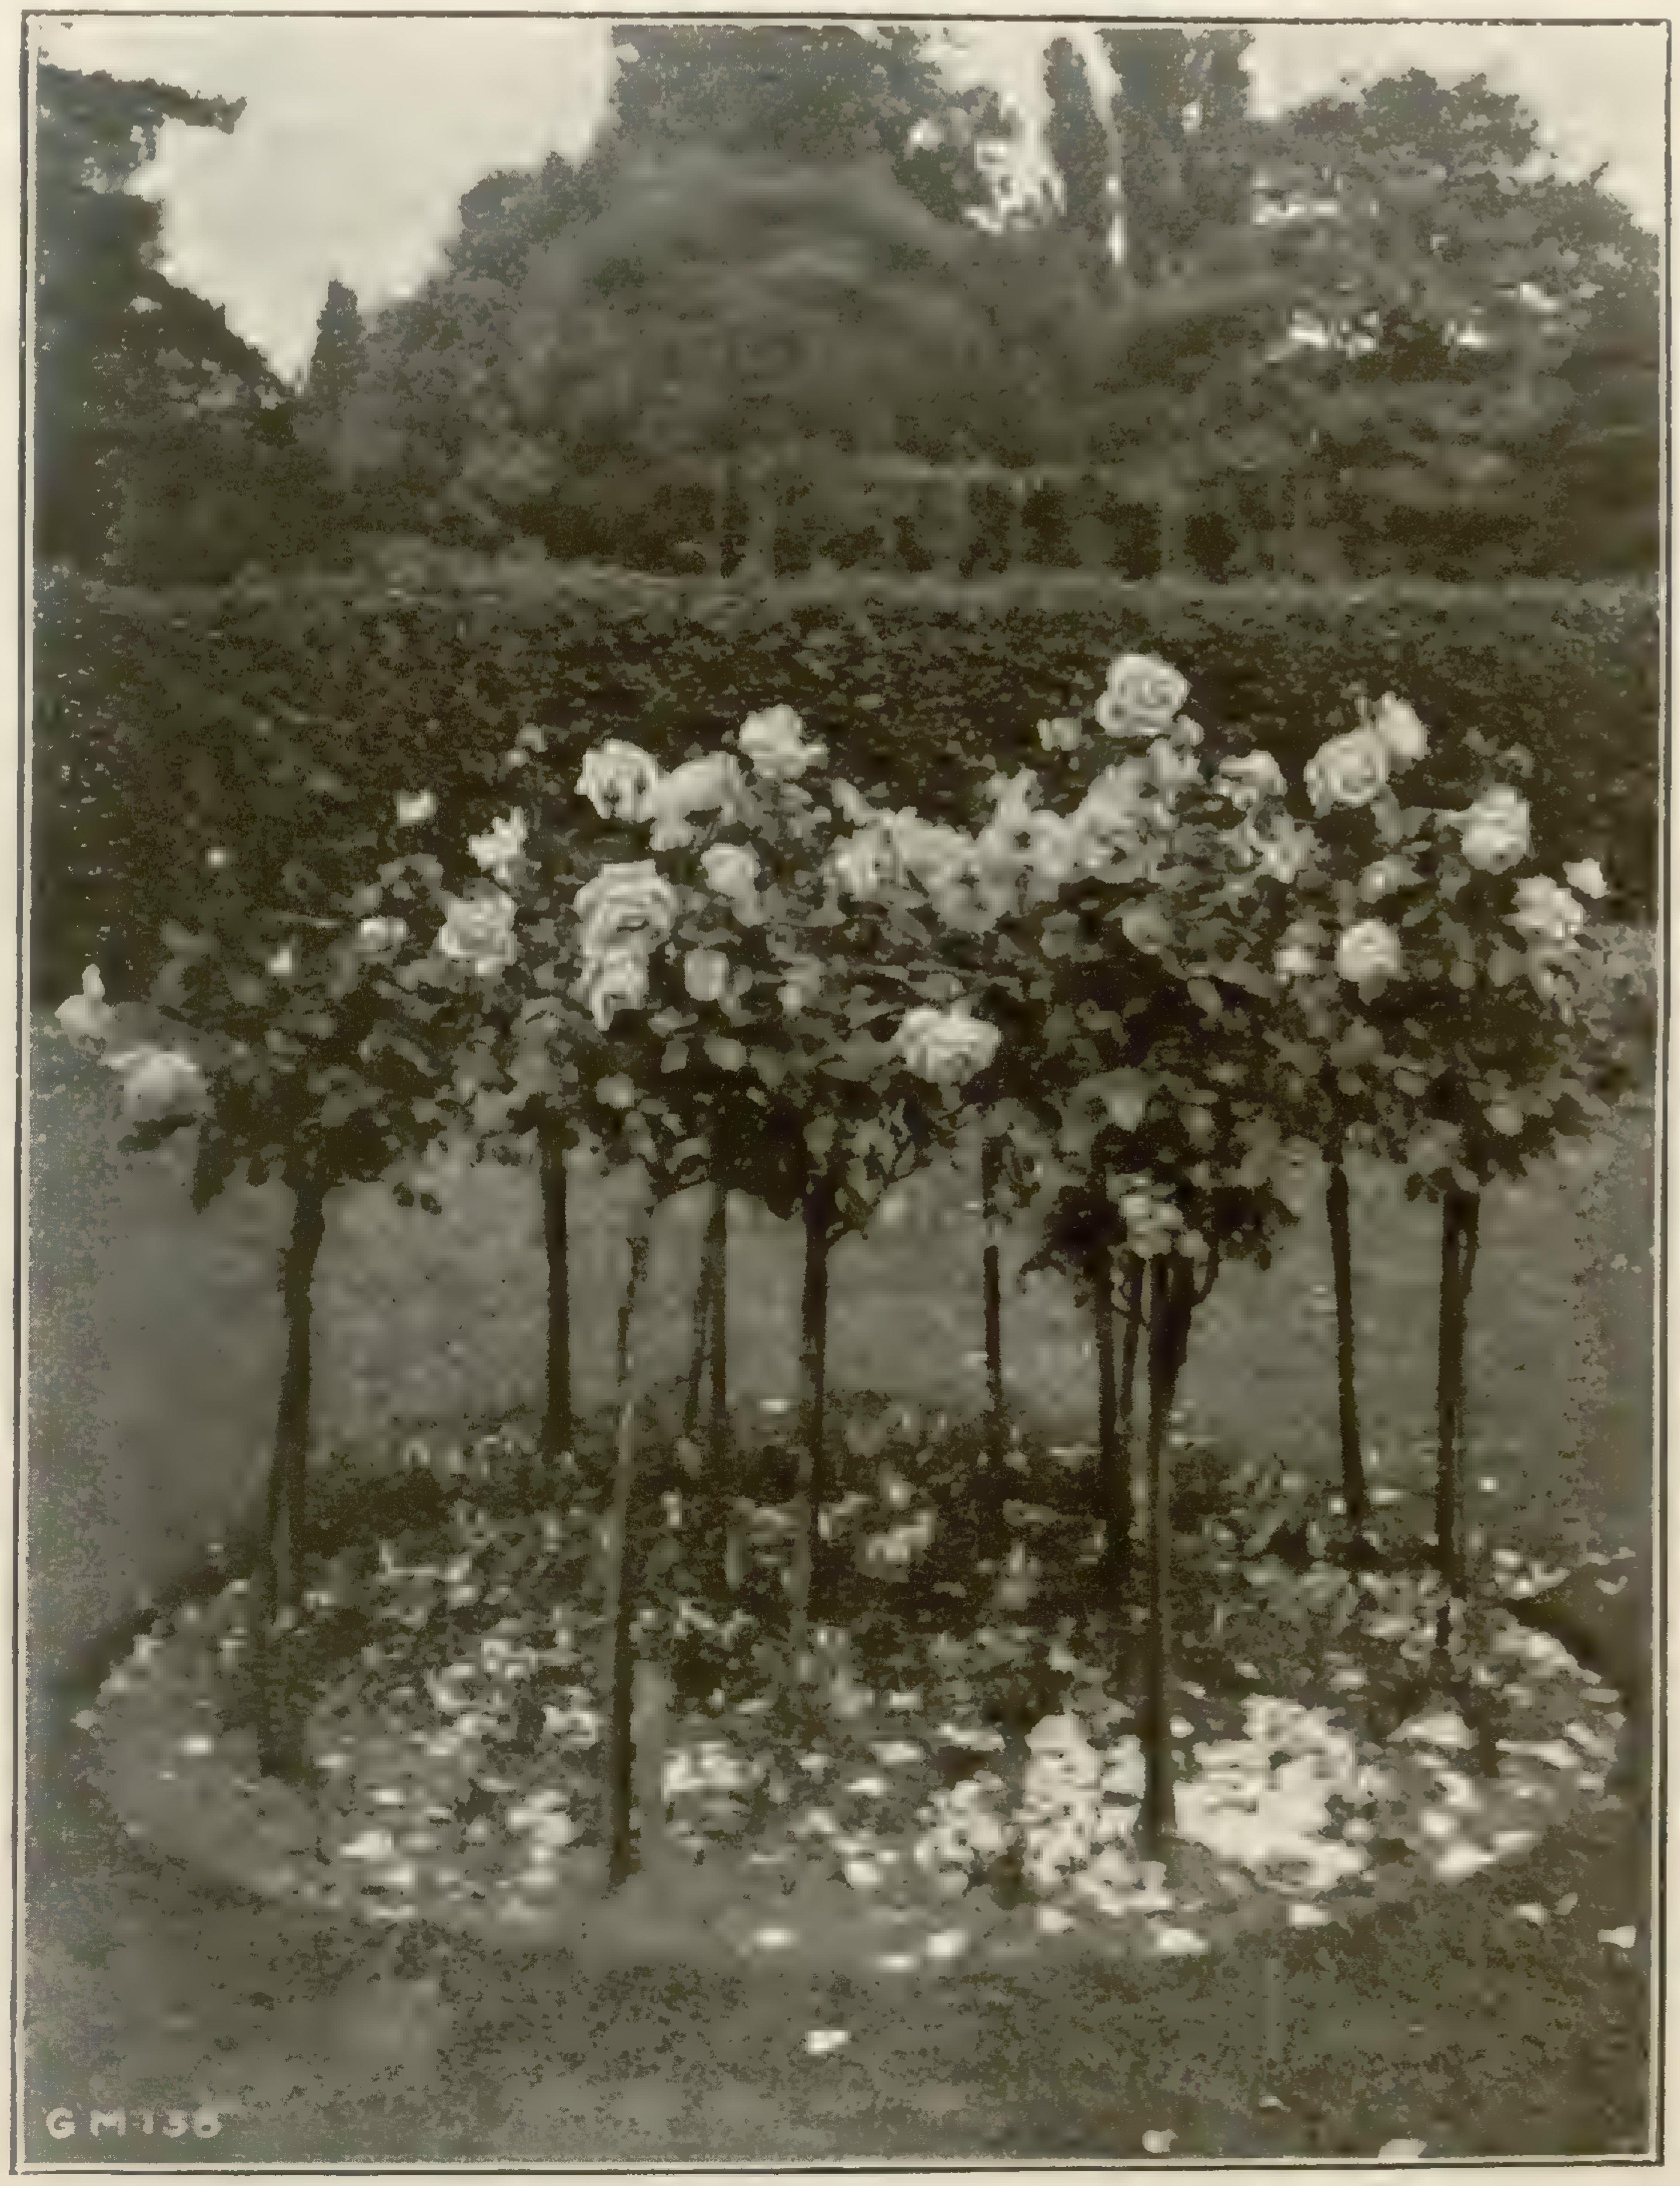
Opinions are somewhat sharply divided with regard to the merits of standard roses, and their advantages and disadvantages as compared with dwarf or bush specimens, although the diversity of views is not so marked as was the case some years ago. Here, it should be understood, reference is made to those standards only that reared aloft have borne, if not the battle, the breeze for many a long year, and not to the tall weeping forms that have sprung into popularity within quite recent times. There is no great difficulty in understanding how this divergence in the views of amateur rosarians has been brought about, when one has had opportunities for visiting a considerable number of gardens, and seeing what is being done in the matter of rose growing. One's opinion on questions of garden practice is necessarily greatly influenced by the results obtained. If they are satisfactory the practice is regarded as a good one, and it is supported accordingly. Should they fail to realise expectations the practice by which they have been brought about, if not strongly condemned, is not spoken of or written about as one that should be followed.

The variability in the results obtained in the cultivation of standard roses fully justifies the diversity of opinion that exists with regard to them. In some gardens they are found in a vigorous state of health, with large heads furnished with an amplitude of foliage, and an abundance of blooms of good size. In others, and these, unfortunately, in the majority, they are lacking in vigour, with small attenuated heads, and with but few blooms, and these of indifferent quality. Let us pause for a moment to inquire why there should be this difference in the standards grown in two gardens that differ but little in the skill that is brought to bear on their management. Standard roses, it should be understood, are somewhat peculiar in their requirements, and do not possess the same degree of recuperative power as the dwarf bush and some other forms. Hence it is essential to success that a good beginning should be made. The English brier, which is so largely used in the making of standards, is a hungry plant, and the rose that is worked upon it soon shows signs of distress if the soil is in a state approaching impoverishment. The age and character of the stock have also considerable influence upon the growth. If the stem is stout and sufficiently youthful for the bark to be still green, the sap will rise freely and supply the rose with the food essential to a healthy growth. Not only is it necessary the stock should be young and healthy, and the soil deeply stirred and liberally enriched with manure previous to planting, but the variety must be well suited to growing in standard form.

Many amateurs fail with standard roses because of their planting them in positions that are quite unsuited to them. The roses are sometimes planted in borders among shrubs, and if the borders are not crowded, and the soil free from the roots of large trees, they usually do well, and present a pleasing appearance; but in crowded borders they seldom do even fairly well. A favourite practice with many amateurs is to plant standard roses in the grass alongside the walks; but as the rose trees, like those grown for their fruits, have an objection to the grass being brought close up to the stems, they have a short, and, judging from their appearance, miserable existence. Occasionally they are planted singly in small beds, and if the soil is well prepared and the beds kept free from deep-rooting plants, and the other conditions being favourable, the results will be satisfactory. More often than not the owner of the garden regards the area so valuable as not to admit of a square foot of the surface being bare, and in giving practical effect to his views he fills the beds with strong-growing bedding and other plants, and, in a few instances, trains nasturtiums or other climbers equally vigorous up the stems, and, it may be, among the branches. The results are an attenuated growth, a few indifferent flowers, and a short life.

From the foregoing remarks my readers will have been able to obtain a fairly clear idea of what to avoid, and we may now turn to consider what should be done to ensure success. The first point that should have full consideration is the selection of varieties. Those who would avoid the risk of failure should not visit the exhibitions note book in hand, and select from winning boxes varieties that attract attention by reason of their large size and fine form. They may do this if they intend growing roses for competitive purposes, but those who would ensure success with standards must visit nurseries and gardens during the summer months, and make note of the more beautiful varieties that have a robust habit, or seek the advice of someone well acquainted with the garden culture of roses. At the close of these notes a list of a few of the best varieties for standards will be given, and if these are purchased and planted they will not fail to form objects of beauty, provided the planting is well done and the subsequent management judicious.

In the purchase of the plants select those only that are in a robust state of health, and where there is room for choice give preference to those with stout, comparatively green stems. With such plants as these a good beginning will have been made, and one may anticipate with some confidence satisfactory results. On the other hand, when the heads are weak and the stems present a grey weather-beaten appearance, there is not much chance of a full restoration to vigour. One can sympathise with the growers in the difficulty they must have in obtaining from the hedgerows large stocks of the briers of the right kind. The difficulty is great, and it appears to me that the time has come when a systematic effort should be made to raise standard stocks on a large scale. With the rugosas, Penzance briers and other robust forms there ought to be no great difficulty in raising home-grown stocks of the right sort, and the suggestion should have careful consideration.



BED OF STANDARD ROSES AT KEW.
The variety, Caroline Testout.

There are various ways in which standard roses may be arranged to produce a pleasing effect, and to these brief reference may now be advantageously made. In a geometric or other rose garden, and in groups of beds on the lawn, it may be well to furnish a few of the beds exclusively with standards, as in the case of the bed of Caroline Testout, of which an illustration is here given. In the majority of gardens, and especially those of moderate dimensions, it is preferable to associate them with dwarfs, as shown in the second of the two illustrations. This bed had not long been planted when photographed, but it was selected as showing more clearly the method of arrangement than one long-established would have done. This latter method is especially suitable for borders, whether near the boundaries of the garden, with a background of shrubs, or in prominent positions on the lawn. Where it is desired to flank a walk with roses it is the best of all methods. In the latter case it will suffice to make a border three feet wide, and then to plant a line of standards and dwarfs alternately along the centre, at a distance of eighteen inches apart. In a large space the border may be four feet wide, and have three rows of dwarfs, and two of standards, the latter being arranged alternately with the dwarfs in the two outer rows. Where there are three rows the plants should be two feet asunder in them. In the one case the standards will be three feet apart, and in the other four feet, but the distance may be varied to suit the taste of the planter, but they should not be nearer than three feet. In arranging beds the dwarfs should be placed about two and a-half feet apart, and the standards four feet; but when both are in the same lines they should be arranged alternately, in which case the two forms will each be five feet asunder. It is not essential to a pleasing effect that there should be but one variety in each bed, but the varieties ought to be of the same height, and the colours be selected with due regard to harmony.

The necessity for thorough soil preparation and subsequent good cultivation has been indicated, and a mere mention of the fact to those who love roses, and desire to have them at their best, should be sufficient. Thorough preparation consists in applying a four or five-inch layer of well-rotted manure from the stable or farmyard, and then breaking up the soil to a depth of twenty-four or thirty inches, and well incorporating the manure with it. Subsequently the soil should be maintained in a high state of fertility by annual or biennial applications in winter of manure, and by occasional supplies of liquid manure during the season of growth. The planting may be done from November till the end of February, in accordance with the usual practice, but whenever carried out the roses should be at once staked, to prevent loosening.

The following varieties comprise some of the very best of those suitable for standard culture: Caroline Testout, H.T.; G. Nabonnand, T.; Dupuy Jamain, H.P.; Frau Karl Druschki, H.P.; La France, H.T.; La Tosca, H.T.; Madame Abel Chatenay, H.T.; Madame Jean Dupuy, T.; Madame Pierre Cochet, T.; Mrs. John Laing, H.P.; Mrs. R. G. Sharman Crawford, H.P.; Ulrich Brunner, H.P.; and White Maman Cochet, T.

Viator.

Planting Climbing Roses in a Greenhouse. — From information received and from personal observation I have come to the conclusion that very few amateur gardeners treat their climbing roses correctly in the first season after planting. The shoots carried at planting time are generally laid in their full length, and, as a consequence, the unripe tips die back, and growth only pushes from the top two or three buds, leaving the base of the plant bare. All shoots found on a climbing rose at planting time should be cut back at least half their length, or to the eaves of the greenhouse, then strong shoots will push from near the base and the lower part of the rose will be well furnished.—E. J. K.

PERPETUAL CARNATIONS.

The "cult of the perpetual carnations" is ever increasing, so that any new particulars regarding varieties or culture is warmly welcomed by growers and others interested in carnations.

Mr. Slade, in his interesting notes on "Seedling Carnations" ("G.M.," January 4), gives a descriptive account of many of his own seedlings, and particulars of the crosses from which they were raised. Many of the crosses made were probably made as the result of a desire to obtain a batch of seedlings which should be as different as possible from the parents from which they sprung, and in this Mr. Slade has been eminently successful.

The notes in question also prove that in many crosses the progeny partakes more closely of the characteristics of the seed parent than the pollen parent, and though this is noticeable in other flowers than carnations, it should not be lost sight of by those who intend to pursue the interesting hobby of seedling raising.

Mark you, however, that though the question of seedlings seems to be largely dominated by luck or chance, in reality it is no such thing, and though a grower may raise a "sterling" novelty by haphazard crossing, yet he has really effected the "right cross," even though it be by accident. Naturally enough, some varieties are better fitted for seed parents than others, and it is by a close study of the varieties, and of the range of colourings in hand and desired, and working upon the results of this study, that success can be made possible.

One of the foremost of America's carnation specialists has laid down a set of rules for his own guidance in the raising of new varieties. These rules are based upon many years close attention, and have been productive of very good results. In selecting parents for crossing the first consideration is for the colouring, and for this the rules have been formulated. All varieties possessing undesirable undertones, shadings, stripes, etc., are put on one side as unfit for the production of first-class seedlings. It must be borne in mind that the seedling carnation which is to gain a true measure of popularity must in all cases be an advance upon its parent, it must be clear and decided in colouring or else it will be of little use, and will never supplant our present forms.

So much for colour then, and for progressive work; to obtain first-class "whites" white must be mated with white if purity of colour is to be obtained. For yellows yellows must be crossed with yellows or with white. Yellow mated with scarlet will usually either give a brighter scarlet or else deeper yellows and orange. Scarlets crossed with crimson heightens the crimson hues, and often affords those rich red shades midway between the two. To produce dark crimsons crimsons only should be used.

All shades of pink cross well, but if clear bright pinks are sought for those which tend to rose and scarlets should not be used. When "variegated" varieties are used for crossing it is wise to keep to the same colour class for each cross. The mauve, lavender, purple, and similar shades should be kept apart, and not used with the brighter colours, as the result would be to render the colours dull.

The Ever-blooming Carnation.

This is the type for the future—the ever-blooming carnation. This is the kind that will pay to grow. To emphasise my meaning, I may say that the true "ever-blooming type" will commence to flower at three months from sowing, and cuttings will go straight away to blossom as soon as rooted. The habit is light (not close and bushy), side shoots are continually produced, and these run to blossom quickly. There is thus no superfluous foliage, and a batch of plants is really always in blossom. Harlowarden will amply illustrate my point; there you have a light-habited variety, with few leaves, long stems, and a regular succession of side shoots which speedily run to flower, and the flowers are good.

There is the object in view, and first-class carnations which are produced on these lines will be always welcome.

The flower and its form are other important points which merit the closest attention; with the English florist the plain-edged flower has always been popular, but his American brethren favour the fringed-edge section. There is a sound reason for this Transatlantic love of fringed blossoms, for whereas the plain-edged flowers travel badly and bruise easily, the finely serrated edges of the fringed blooms protect the petals from injury to a great degree. The plain-edged varieties are, of course, first and foremost in point of beauty, and many seedlings are now being raised (particularly by some of the Guernsey raisers), which are of this character.

Apart from this, the flower, to be of value, must neither recurve nor incurve. Incurving petals make a blossom look partially faded, while the recurving petals make the flowers look poor and faulty. The outer petals should expand horizontally, and above these the inner ones should be arranged symmetrically, culminating in a high, full centre.

Sundry Points.

It may be noted in any collection of perpetual carnations that the foliage varies very much in colouring. In some varieties the leaves are pale green, in others the hue is a deep bluish-green, and though each of these may produce fine flowers, one can say with a great amount of certainty that those with the deep bluish foliage have the stronger constitution, a point that should not be lost sight of in the raising of seedlings.

We may hear of many sterling novelties in the near future, and the "Channel Islanders" will be well to the forefront with new varieties. Among their acquisitions at the present time we may note the fiery red Louise Michel, raised by Mr. Maurice. Then there is Mr. Lancashire's Rose Doré, which was shown at the recent show at Regent's Park, and of which more will be heard. The same grower has also a grand pure white, which promises to be of exceptional merit. Messrs. Bell and Sheldon, too, have a splendid new white variety, so that the standard varieties must expect some keen competitors shortly.

A carnation popular in Guernsey is the bright rose-scarlet Sarnian, which will be extensively grown for cut flower purposes. Mr. H. Burnett's novelties, which embrace such favourites as Mrs. Burnett, Marmion, Ceres, and Aurora, also include Cassandra, a large fragrant rose-pink; Daphne, a deep rosy gem, of moderate size, but very free; Rosalind, a white ground with pink markings; Miranda, which can be described as an improved Prosperity; and the rich heliotrope-coloured Mikado, which is novel in colouring, and strong in growth.

P. S. Hayward.

Mr. H. W. Weguelin's book—Carnations, Picotees, and Pinks, will tell you plainly how to propagate and grow these favourite flowers to perfection. The work is freely illustrated with plates of leading varieties, and explanatory diagrams as to layering, taking cuttings, fertilising blooms, etc. Price 2s. 6d. net by post, in box, 2s. 10d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

HITHER AND THITHER.

In an interesting article published recently Mr. Alger Petts observed that "the interest of a garden is immensely increased if the owner makes a speciality of some particular flower." I quite agree with him, and it is to this spirit of specialising that we owe so much. Floral tastes wander in different directions, as they should in order that nothing that is worthy should be neglected, but, take what flower you will and study its history and development. In close connection with the latter you will find the names of specialists, men who loved the flower, lifted, it may be, from the common place, as Eckford did the sweet pea, and Peter Barr the daffodil, and centred on it the force of undivided attention. This is the way by which flowers are improved, and though the man who specialises may work alone for a time he is by no means a plougher of a lonely furrow, for others catch the spirit, and he soon finds himself one of a band of interested enthusiasts.

Nor is specialising confined to individuals who have large gardens and money to spend on this or that flower, for the spirit moves amongst cottagers and amateurs who move in lowly spheres. Perhaps these men do not raise new varieties, nor do much towards the further development of the flower they love best, and they benefit rather from the efforts of others in the enjoyment they get from the new varieties that come out. Still they are specialists and worthy of the name, as scores of illustrations show. I think the finest specimen fuchsias I have ever seen were grown by a working shoemaker in a home-built greenhouse in the heart of a great town. He cared but little for any other flower; fuchsias had all his affection. In short, he was a specialist. So is another man, a bargeman, by the way, but his forte is roses, standards which he buds with his own hands. His garden is full of them, as novelties are sent out they are added to the collection, and since he took up his abode in the village where he lives, a number of his neighbours have taken up rose-growing. It is true that the spirit of specialising is infectious.

It is quite refreshing to read an article from the pen of a single-handed gardener who commences by stating that he belongs to this large section of the community, and I can assure Mr. H. Roberts that I was very much interested in his remarks. The article in which your correspondent talks to gardeners on page 36 is like some sermons that are simple, it is impressive. It teaches a lesson to young gardeners, namely, to use tact. Just so, the gardener needs horticultural knowledge and also tact, and he must be a student of human nature as well as of plant life. The master, the mistress, the daughters, the children, yea, even the cook, they must all be considered, as Mr. Roberts aptly points out, and doubtless he has succeeded in doing it; but then I take it that he has reasonable people to deal with, and some poor gardeners, single-handed and otherwise, are not so fortunate in this respect.

Regarding the reference on page 22 to the use of grease bands round fruit trees as a remedy for the winter moth trouble, I would say that the place to see grease-banding done on something like an organised system is in that famous fruit-growing district known as the Evesham Valley. The Evesham fruit growers, by the way, are a hard-headed set of men, but they have proved the value of grease-banding, and they believe in it, almost without exception. It is true that some of them are careless and merely daub the stems of the trees with the grease, which is a mistake, as it is not good for the bark, but the result of this co-operative method of dealing with winter moth is the means of keeping down what would otherwise be a serious evil. Recently I visited a number of plantations round Evesham, and observed scores of trees on which the bands were thickly studded with male and female specimens of the winter moth. What would have been the result next season if all these pests had been allowed to live?

Catalogues are coming in with a rush just now, and most gardeners have quite a pile of these interesting publications. The sending out of catalogues is, of course, the seedsman's sprat with which he hopes to capture the mackerel, but I fancy that many in the trade would feel disappointed if they knew what a number of their catalogues are never stripped of the wrappers. Of course, this is inevitable, because you cannot deal with every firm that tempts you with a catalogue, or one would soon be in a state of bankruptcy. If plants and flowers have increased in number and improved in quality, so have catalogues, and the seed lists of leading firms to-day are bulky and elaborate publications, which do credit to the artists, photographers, colour printers, and, indeed, all who help to make them up. Perhaps, if catalogues were a little less elaborate, seeds would be cheaper, but there, that is part of another story.

AN EXCELLENT ARRANGEMENT OF DWARF AND STANDARD ROSES.

Let me pay a word of tribute here to the trade that has done so much to improve horticulture by the introduction of almost endless varieties of fruit, flowers, and vegetables. The tradesman knows the value of novelties if they are good, and the considerations of business compel him to cater for the public in this direction, but he has no control over a new introduction after it leaves his hands. The man who invents a new machine can protect it by means of a patent, but not so the nurseryman, who may have spent as much time and patience over a new plant. All he can do is to keep the stock until he has sufficient to recoup himself for all his trouble, before he puts it into the market. Of course, private individuals also raise new plants, but it is the trade that distributes them, and, but for the competition of business, it is not too much to say that the horticultural world would never have had many of the treasures it now possesses.

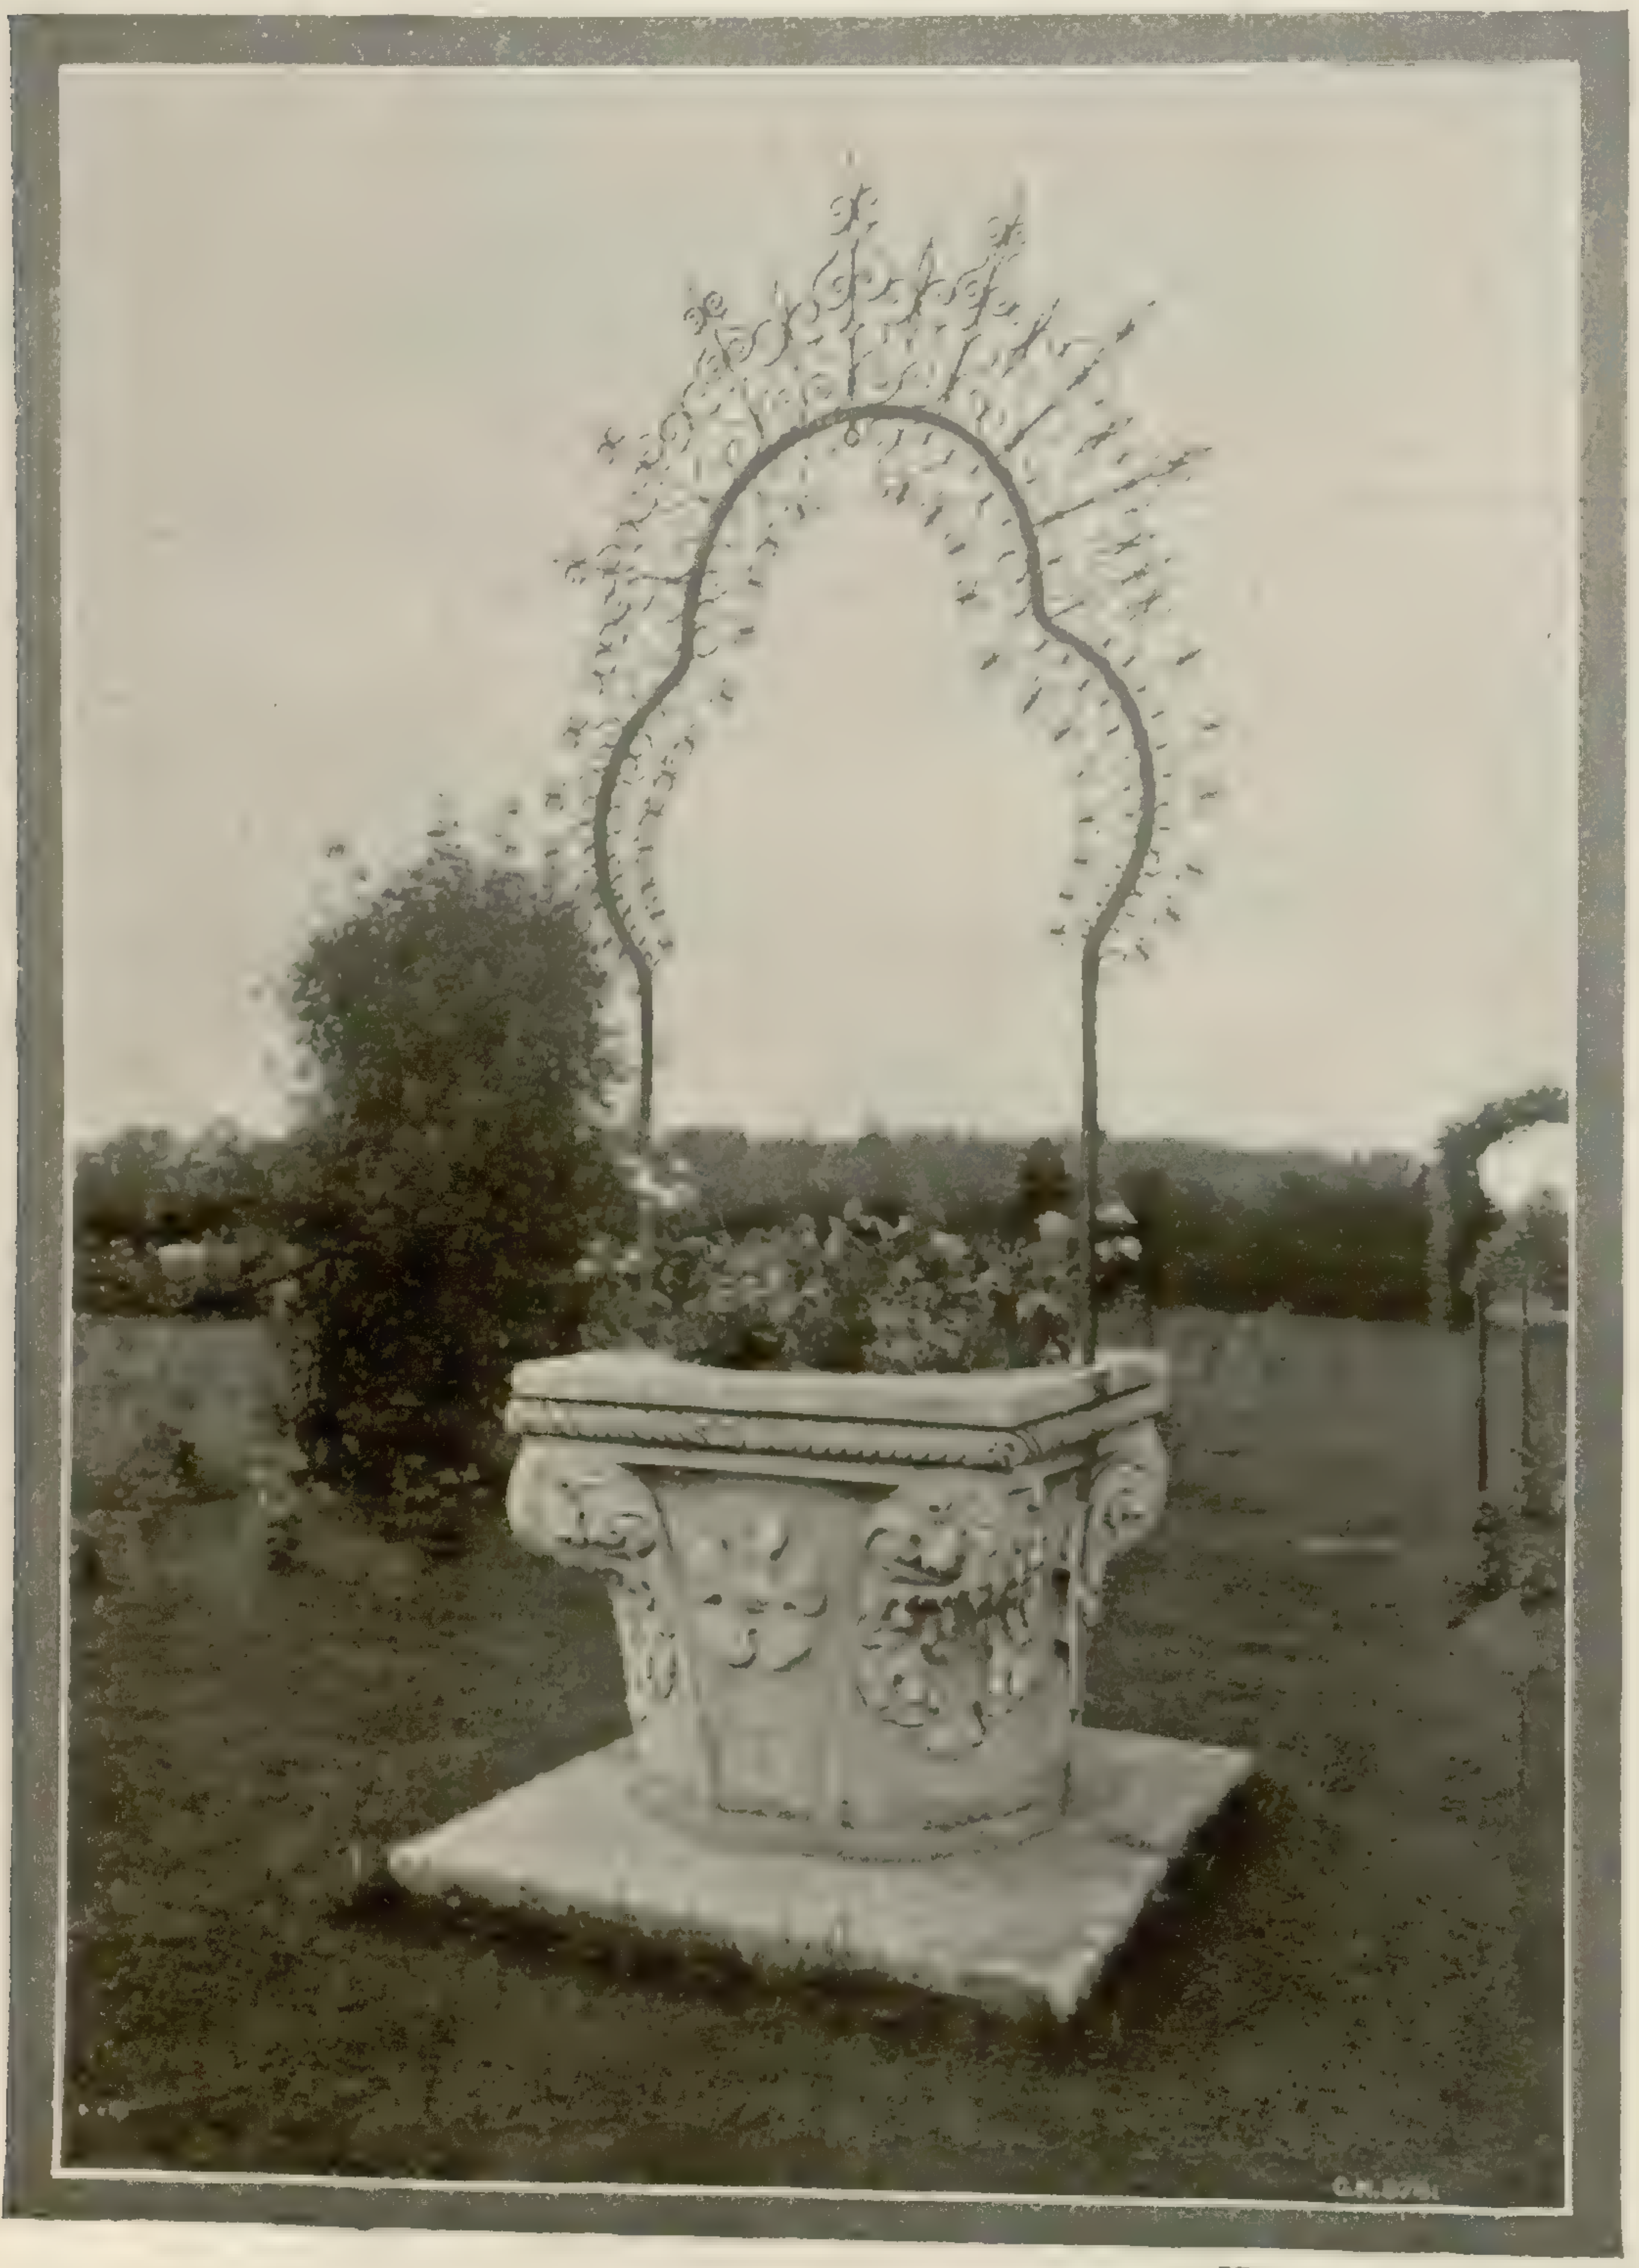
When I was a boy I hadn't the usual boyish ambition to go to sea, but I longed instead for the life of an orchid collector. This was the result, no doubt, of reading the reminiscences of one of the fraternity, telling of hairbreadth escapes and thrilling adventures in tropical climates when in search of orchids. I pictured myself penetrating an unknown region, and imagined myself coming home in triumph with such a floral wonder as the civilised world had never seen before, and myself, of course, the hero. Needless to say, my early dream was never realised, and such ideas are hardly entertained by the boys of to-day, for the vocation of the orchid collector, like that of buccaneer of old, is gone, or nearly so. The hybridist and raiser at home has knocked him out, and there is little need to scour the world for orchids now that the difficulties of propagation are mastered, and the raising of orchids from seed has become a comparatively easy matter.

Taken as a whole, the life of a young journeyman gardener is by no means unpleasant, and there would be little to complain of if prospects were better, but he is not altogether to be envied when he happens to be on duty at night and the thermometer is registering twenty degrees of frost. Some of you, my readers, have had that experience (perhaps some are having it now), as also has the writer, who has vivid recollections of marching lamp in hand at midnight from boiler to boiler situated a long way apart. One felt in those days that the modest twelve shillings which came in on Saturday night was being earned (we didn't get duty pay), but it had its redeeming feature, for one could eat such a meal by the bothy fire after banking up at midnight that it would be dangerous to try now with any hope of sleeping after it.

Spy.

GARDEN ARCHITECTURE.

There are few matters in which greater taste and more refined judgment are required than in the introduction of architectural features into our gardens. As a rule, well-grown plants are the best decorations, but there are many who think that architectural adornments add to the beauty of a garden, and when this is of the formal type, and especially when it is in juxtaposition to the mansion, such a standpoint has certainly something to commend it. At Versailles, and in many Italian gardens, sculpture has been allowed to intrude into what should be the gardener's domain, with the most unsatisfactory results. In many cases the effect is absolutely ludicrous, the exquisite proportions of the statuary and vases being entirely lost owing to their incongruous setting.



[Photo: F. Mason Good.

AN OLD VENETIAN WELL-HEAD AS A GARDEN ORNAMENT AT TYLNEY HALL.

Statues are out of place in an English garden. If they are valuable works of art they deserve a protecting roof, for in our climate they soon become ruined by the weather; if they are without merit, as the majority of them are, their mere existence is an offence, and they may well be included with those to which Lord Rosebery referred when he said, "If those restless spirits that possessed the Gadarene swine were to enter into the statues of Edinburgh, and if the whole stony and brazen troop were to hurry and hustle and huddle headlong down the steepest place near Edinburgh into the deepest part of the Firth of Forth, art would have sustained no serious loss." Bacon also wisely wrote, "They add statues and such things for state and magnificence, but nothing to the true pleasure of the garden."

As a matter of fact, it is not possible to overestimate the care with which a selection of architectural objects should be made, so that they may take their right proportion in garden schemes, and with so many opportunities of seeing how this should not be done, and with some thought expended on the ultimate harmony of the effect, there is no reason why anyone, with the opportunity of choosing good and artistic specimens of stonework, and with a true appreciation of landscape beauty, should not be enabled to add materially to the charms of his garden. Many indeed are the nooks and corners in a garden where a well-placed urn, vase, or well-head may be of great value, throwing the far-seen views into still greater perspective, and emphasising the attractions of its own particular setting. If the ornaments used are not of a character which corresponds with the other stonework of the garden, then, indeed, their value is lost, and they become interlopers, whatever beauty they possess in themselves being nullified by their lack of harmony with their surroundings.

What can be more unpleasing than the sight of marble vases, urns, or such-like ornaments, lovely in themselves and in the Italian landscape from which they were torn, arranged along the sandstone terrace or gravel walk of a red-brick English dwelling? Even in the garden of such a house they would be out of place. all the stonework surrounding it should correspond in colour with the walls of the house, and, in view of the beautiful designs in urns, sun-dials, and fountains that are procurable, it should be an easy task to make the garden at once lovely and in keeping with the house to which it forms the setting. The warm, rich colour of red stone against the dark green of the trees, the blue shadows and tones given it by distance make such ornaments of incalculable value in an atmosphere too cold and grey to endow the marble of the south with the warmth of colour which transforms it into such a thing of beauty in a sunnier land.

The old stone well-heads, such as illustrated, and vessels of bygone centuries will beautify our gardens if they are softened down with such features as will cause them to blend with their surroundings. Imbedded in flowering creepers, which, clinging about the foot, serve to accentuate rather than to hide the pedestal from which the great carved bowl rises, one of these old vases forms a lovely picture, and looks as if it had always belonged to the particular spot in which one finds it, and had become as much a part of the garden as the very trees and flowers themselves, carrying the same message of age and tranquility as the great oaks in whose shade it stands. The end to be striven after in the arrangement of stonework in the garden is that it should form part of the landscape and not be merely an object set down in it; and if the fact that the hand of man placed it there can be obliterated, and its position and setting appear so natural that it conveys the idea that it is an incident in the view the success of its position is assured.

Another important point is that whatever stonework is set up should be useful, and its reason for its position in the landscape obvious, for without utility there is no real art, and the stone vase with no meaning or use to which it could be put becomes ridiculous. It is extraordinary that with so many artistic examples of stonework, both of our own day and of the centuries behind us, we should see so many hideous examples in our gardens. Particularly in fountains has the tortured brain of man evolved weird shapes and fantastic outlines, which force themselves on eye and brain with all the horrible fascination of a nightmare—a nightmare frozen in stone. Yet what beautiful forms are to be had for the copying, or are sometimes to be found by the fortunate in out-of-the-way corners.

In an old garden, rich in stone terraces, where clipped yews throw shadows on the grey steps and paved ways, is a fountain to all appearances as old as the garden itself, and contemporary with the balustrade of the terrace above, yet it has only been in position eighteen months. It is an old granite cider trough, circular in shape, and about six feet in diameter, and was discovered half-buried in the mud of a farmyard. It is now set in the centre of a quiet lawn, surrounded by a pavement of harmonising stone. From a central fountain-head, hidden by rocks, clear water rises to a height of five feet, sparkling in the fitful gleams of sunlight, and falling in the low trough with a musical note, while dew-bright drops glitter on the enclosing stones. Yet another instance illustrating the happy use of garden ornament.

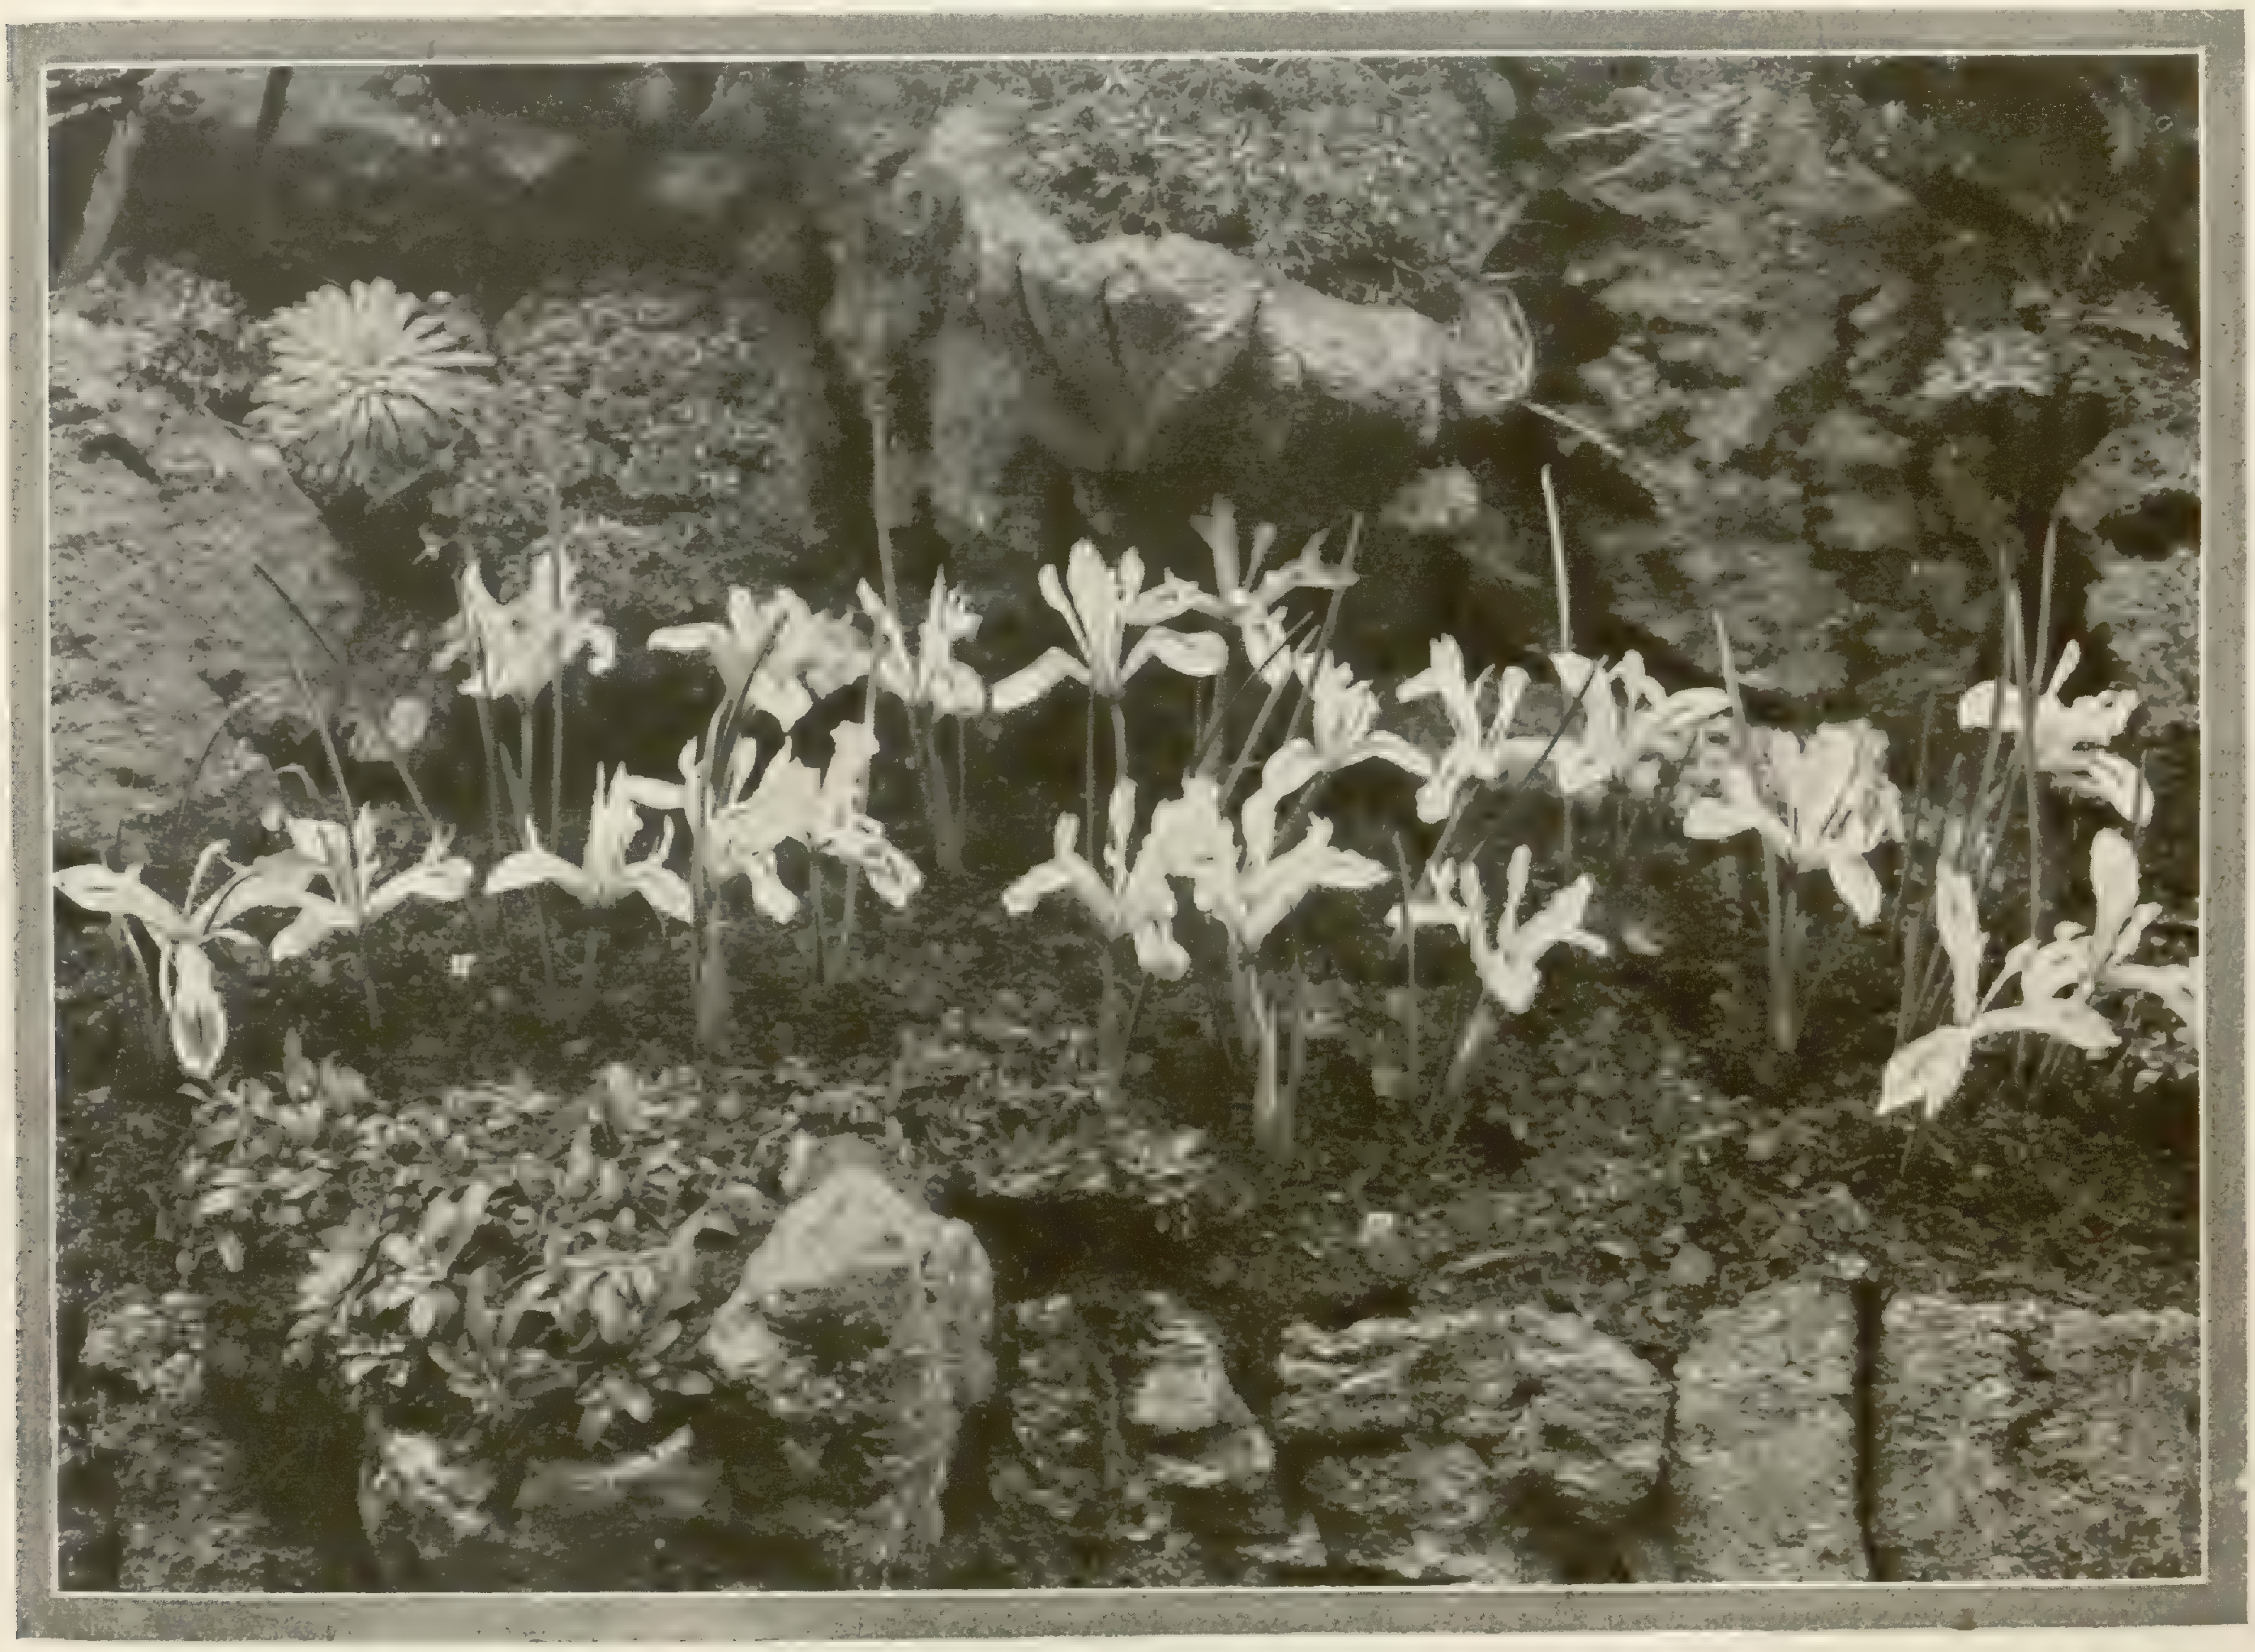
In a garden overlooking the mouth of one of the loveliest of west-country rivers is a walk, bordered on the river side by a low, wide wall, fern-studded and lichen-grown. On the wall stand at intervals tall and finely-shaped Italian wine jars, brimming with the sweetness, not of southern wine, but of fragrant English pinks, that crown every vessel as with snowy foam and perfume the evening air with their sweetness, while they delight the eye with the harmony of their grey-green grass against the warm red of the old earthenware. S. W. Fitzherbert.

Metropolitan Window Gardens.—The Earl of Meath, President of the Metropolitan Public Gardens' Association, again draws attention to the desirability of inducing London householders to cultivate plants and flowers in window-boxes, baskets, etc., for the purpose of adding a cheery aspect to the streets and gladdening the passers-by as well as the inmates. In 1907 a series of prizes was offered for the best efforts in window gardening, by this association, and there were 140 prizewinners out of 450 entries. The Earl of Meath is now arranging a competitive scheme for the present year, and he will be delighted to receive contributions towards the prize fund at the association's offices, 33, Lancaster Gate, London, W.

THE RETICULATA IRISES.

Among the fairest flowers of our gardens are the irises, a race of plants familiar to all generations of flower lovers, and never more prized than now, when the search for new plants and the work of hybridisation and seedling raising have given us so many beautiful new forms. It is needless to press home this point to the mind of the reader, as everyone is familiar with one or more of the exquisite irises whose almost bewildering variety affords us a choice greater than we can well limit to a few species or varieties.

Even when we think of the noble irises of summer, with their still more opulent beauty, we cannot but delight in the graces of their earlier sisters who dare the uncertain spring of our climate, and from an early period give us their exquisite flowers and sojourn with the snowdrop, the crocus, the early scillas and glories of the snow, finding in them no superiors in beauty or in grace.



GROUP OF IRIS HISTRIOIDES, EXHIBITED BY MESSRS. W. CUTBUSH AND SON AT A RECENT R.H.S. MEETING.
The flowers of this Iris are bright blue.

And of all the early irises, now more numerous than ever before, there are few so much admired as the forms of Iris reticulata, the netted iris, whose blue and gold or purple and gold (true regal colouring) blossoms afford us endless delight in their season. The section called the reticulata group includes a few species not perhaps coming precisely within the range of the typical I. reticulata and its varieties, but as all possess the beautifully reticulated bulb, whose netted covering well repays close investigation, either with the naked eye or the microscope, they cannot well be considered separately. One may, however, omit the allied I. Sisyrinchium, which has the reticulation of a different pattern, and has a much shaggier and thicker covering than that of the iris under notice.

Broadly speaking, the reticulata irises are widely distributed in several parts of Asia, the typical reticulata and Krelagei coming from the south-eastern Caucasian region; cyanea from Armenia; sophenensis from Central Asia Minor; Histrio from Palestine; and histrioides from the neighbourhood of Amasia. Vartani is found in the neighbourhood of Nazareth; Bakeriana comes from near Mardin between Armenia and Mesopotamia, and Danfordiæ or Bornmulleri from the South of Cilicia, and from the Amasia region of Asia Minor. All of these reticulata irises have ovoid bulbs, netted coats, sessile flowers, and, with the exception of Bakeriana, four-sided leaves.

I. reticulata.

This, called the type, is, as the late Sir Michael Foster told us, probably not the real typical flower, what we know as the variety Krelagei being the more common plant in its native habitats; seeds from I. reticulata generally produce Krelagei. However this may be, the form has been long recognised as I. reticulata, and it must be adhered to for practical purposes. It has long strap-shaped falls whose violet-blue coloration is brightened by a white middle ridge, decorated in the centre with a line of orange, and a yellow, dotted streak along the claw, also of a beautiful blue. The whole effect of the beautiful form of the flower and its colouring is exquisite, while the delicious violet fragrance it exhales adds to its attractions. The leaves, which are of some length when the flower opens, are four-sided, with a horny point.

I. reticulata Krelagei.

Although the colouring of Krelagei more nearly approaches the royal colouring of "purple and gold," it is not so pleasing as that of the typical plant, although some of the varieties are much brighter than others — red-purple, plum-purple, and almost black purple existing in the range of coloration. It differs from the type in other respects, as it is seldom fragrant, and has generally a shorter and broader character all over its parts. It is, however, so variable that the different characters are difficult to define with certainty. It generally blooms before I. reticulata, but is irregular in this respect.

I. reticulata Histrio.

Sometimes accorded specific rank, there are now few who would recognise enough in its general characters to justify this, and it may be conveniently dealt with as simply a variety of reticulata. For garden purposes it is less valuable than the type, seeing that it is not particularly hardy, and in many gardens is so much weakened by occasional injury to the leaves, which are produced very early, that it dwindles away in the open. The flowers may come as early as December, and may linger until March, while, as the leaves—not too hardy—are about a foot long when the blooms open, it is easy to understand how difficult this iris finds it to accommodate itself to our winters. It is a very beautiful iris with the fall of a reddish-blue with a large centre of white adorned with blue spots and veins, and a yellow ridge, while the standards and styles are blue. It is an excellent subject for pot culture, but, save well south, a difficult one to maintain in health.

I. reticulata histrioides.

I look upon this as one of the best of all the reticulata group of irises, as it stands the weather well, although some think the leaves rather long in proportion to the height at which the flowers are produced. The flower of this variety appears before the leaves, and is a charming one, not unlike that of Histrio, although it varies considerably in its shades and markings. It is also variable in time of flowering, but I have found it one of the most amenable of the group to cultivation in the open-air. It generally blooms in the open about February or March, when its blue, white, and golden flowers are very beautiful. The illustration shows this iris as exhibited by Messrs. William Cutbush and Sons at the Royal Horticultural Hall on January 14.

I. reticulata sophonensis.

This handsome variety, which hails from Asia Minor, near Kharput and Mardin, has secured the name of sophonensis, from Sophene, the old name of the Kharput district. It is one of the earliest of the set, following Histrio, and coming in before any other. The leaves are barely through the soil when the flowers appear, and the latter are very beautiful with their metallic colouring, varying from purple of different shades to lilac. The usual orange ridge is present on the flowers, and they are more spreading than those of the typical plant.

I. reticulata major.

This, the noblest of all the reticulata irises, is said to have been raised originally by the late Rev. J. G. Nelson, of Aldborough, but it appears to have been distributed from other sources. It is larger in all its parts than the type, and the fine deep violet and gold colouring shows to advantage on the larger flowers. This form is scarce in cultivation, but I had a bulb or two from the late Mr. James Allen years ago.

Other reticulata varieties.

The other varieties of I. reticulata proper are not of sufficient importance for the garden to merit much detail. Of these the best is cyanea, an indigo blue one; caerulea, slatey-blue; and purpurea, close to Krelagei, and of a deep purple. It differs in a few features from Krelagei, and is superior to that form as it is frequently seen. Other varieties have been raised or collected, and Herr Max Leichtlin has raised some handsome seedlings which he has distributed under garden names.

Dumfries. S. Arnott.

WEATHER AT ROTHAMSTED IN 1907.

The meteorological records of the Rothamsted Experimental Station, Hertfordshire, show that the year 1907 was characterised by a deficiency of rain, and a deficiency of bright sunshine, and that upon the whole it was a year of gloom.

The total rainfall for the year was nearly 27½ inches, showing a deficiency of about three-quarters of an inch. There were seven months recording a low rainfall, and five months giving an excess.

The mean temperature of the year was 47.9 degrees, being exactly the average record for this district for over the past 29 years. There were five months below average, and seven months above average, the great feature of the year being its low night temperatures.

Bright sunshine amounted to 1,557 hours, or 49 hours below the average record at Rothamsted. During the year the sun shone, on an average, 4 hours 16 minutes on each day, as against 5 hours per day in 1906.

The three first months of the year were noted for their small amount of rainfall and their high record of bright sunshine. March was the month of highest sunshine for the whole year, when a total of 206 hours was experienced, which is 92½ hours in excess of the average amount for this neighbourhood. The large quantity of bright sunshine for March caused the ground at one foot deep to be 5 degrees warmer than is usual for the time of year, which was beneficial for the germination of small seeds in the garden, and for spring-sown corn.

April was the wettest month experienced at Rothamsted for the past twenty-five years. There were seventeen rainy days and three slight falls of snow, giving a total of nearly three inches of water, or one inch in excess of the usual average. April, June, and October were the months of greatest rainfall, over 11 inches being measured during these three months. September was the month of largest deficiency of rain, there being a falling off from the average of 54 years of nearly 170 tons of water on each acre of land.

June weather was generally showery, cold, and dull, and both grass and corn crops were exceedingly backward. The ears of corn were a considerable time in pushing themselves free of the sheath, which is always a sure indication of a low yield of grain per acre, although there may be an excess of straw, as was the case in 1907. The flowering time of the grain crops was about a fortnight later than is usual at Rothamsted.

Hay harvest did not commence until the middle of July, and, in fact, there is but little really good well-cured hay to be found from the 1907 crop. As one travelled about the country it was no unusual thing to see a field of meadow hay still uncarried, but bleached and saturated with rain, in the second week of August.

September, with its glorious weather, seemed to come, as it were, to atone for the shortcomings of the months immediately preceding, and registered 185 hours of bright sunshine, or 24 hours in excess of the average, while the mean temperature was 57.6 degrees, showing 1.8 degree above the average. Corn harvest did not become general until about the middle of September, being about three weeks later than usual.

October was a month of excessive rainfall, and over-average temperature, but deficient sunshine. Both November and December gave more than normal temperature and over-average sunshine. December, the last month of the year, was noted for its extreme mildness, the mean temperature being 2.2 degrees above the normal. There were several days when the warmth was as great as during several days of May. In the flower gardens around this district were to be seen many blooms of roses, pansies, violets, and primulas.

Calculating the total rainfall of 1907 to the tons of water per acre, we find that during the whole year 2,768 tons of water have fallen on each acre of land, and if it had not been for the excessive rainfall of October and December, which recorded 828 tons of water in excess of the average, the underground water supply of this district would have been abnormally low, resulting very probably in a water famine.

Harpenden. J. J. Willis.

MIGNONETTE IN WINTER.

Mignonette sown in July, and grown expressly for bloom in winter, becomes well established before frost and fogs set in, and if due care is given in watering, and a comfortable and even temperature maintained, growth continues to advance, and good heads of bloom are produced in plenty. The batches raised for spring bloom, the plants being comparatively small, frequently collapse or become so patchy that they are not worth retaining. Very often late-sown batches are allowed to become saturated while standing in cold frames, and although the young plants may look green and healthy when removed to the greenhouse for the winter, the delicate young roots cannot assimilate the moisture, and the leaves gradually droop and die.

Winter mignonette must have a pure atmosphere. It cannot endure fog or smoke. Some recommend keeping the soil in a dry state, but if this is carried to extremes the roots soon suffer, and then, should water be freely given, the roots cannot take it up, and the plants die. It is not advisable to use liquid manure for these late, small plants, as the roots are easily injured during winter. February is quite soon enough for the use of liquid manure.

Plants that are grown to bloom during March may be made to do double service, instead of being thrown away. If a few of the best are potted from six-inch pots into ten-inch pots, and placed in a warm moist peach house, it is astonishing how freely they will grow, and they will yield abundance of blooms through the early summer months. Plants in full flower in midwinter are best kept in a temperature of from 55 to 60 degrees, and both growth and bloom trusses are much improved by weak applications of warm liquid manure.

Ashwellthorpe Gardens.

NEW BOOKS.

THE SWEET PEA ANNUAL.

Edited by C. H. Curtis and H. J. Wright.
(C. H. Curtis, Adelaide Road, Brentford.)

The issue of the Sweet Pea Annual for the current year is in some respects an advance upon its excellent predecessors, and forms an admirable model of what the official organ of a special society should be. It might appear somewhat extravagant to some who are not sweet pea enthusiasts were we to say that the publication is worth the minimum subscription constituting membership of the National Sweet Pea Society; we will therefore avoid the risk of a suggestion of extravagance of statement by stating that it forms an important part of the advantages enjoyed by the members. The contents, as usual, are varied, interesting, and useful, and have a special value as representing the views and experiences of the cultivators and others who take an active interest in sweet peas and the society identified with them.

There are as usual a number of special articles all more or less good, and the most noteworthy of these are "More Hostorical Notes," by Mr. S. B. Dicks; "Impressions," by Mr. Atlee Burpee; "Germination of Seeds," by Mr. Charles Foster, who, it will be remembered, conducted the society's trials in the University College Gardens, Reading, in 1906 and 1907; "Wire Netting," by Mr. G. W. Leak; "Sweet Peas in New South Wales," by Major Nedwell, North Brighton; "The Popular Vote for Sweet Peas," by Mr. G. H. Mackereth; "Breakers Ahead," by Mr. W. P. Wright; "Adherence to First Principles," by Mr. George Gordon; and "Sweet Peas in Devonshire," by Mr. R. Bathurst. Of special value, both to traders in and growers of sweet peas, is the catalogue of sweet pea names prepared by Miss Jessie Cuthbertson, which contains all the varieties that it has been possible to obtain from the lists of raisers and distributors. The catalogue is so full and admirably compiled that all concerned with the sweet pea are under a debt of gratitude to Miss Cuthbertson for the valuable service she has rendered. Valuable, however, as the catalogue is, it would have been still more so had the year of introduction been also given. This would have added materially to the difficulties inseparable from the preparation of so comprehensive a catalogue as this, but a lady of Miss Cuthbertson's ability would have successfully contended with them. The report by Mr. C. Foster on the Reading trials is admirably written, and will be found extremely useful to cultivators who are not well acquainted with varieties. As seed sowing will soon become general, the following extracts from Mr. Foster's article on the germination of the seeds of sweet peas is of special interest at the present time:

"In the spring of 1907 many purchasers of sweet pea seeds were much annoyed because varieties they had paid fancy prices for failed to grow, and the trade and the gardening Press were kept busy offering explanations as to the cause of failure. With regard to this subject the 1907 trials were most interesting, as the following remarks will show.

"All seeds received for the trials were sown in pots on February 24, twenty seeds of each variety being sown. Many of the varieties germinated very evenly and quickly, but others made no progress. We allowed these dormant seeds to remain until March 20, twenty-four days after sowing, and then went systematically over all the pots where the seeds had failed altogether, or in part, to grow, and were relieved to find that the seeds had not decayed, the outer covering being as hard as that of a canna seed and as impervious to water.

"In six stocks the seeds had all failed to germinate; five stocks had one seed, five had two seeds, four had three seeds, seven had four seeds, four had five seeds, one had six seeds, and two had seven seeds germinated. Thus 136 pots were gone through to find the laggard seeds, each of which then had a portion of its outer covering removed with a sharp knife, and in a very few days every seed was pushing its growth through the soil, even in those cases where not one out of the twenty had previously shown any signs of life.

"It is interesting to note that, with three exceptions, the thirty-four stocks that failed up to the stage named, were all of them new seedlings of quite recent introduction, and it is possible that they were over-ripened and too fully hardened before being harvested during the hot summer of 1906. It is also interesting to note that nearly every variety that failed to germinate had dark seeds, and that many of the flowers were maroon, blue, purple, and of the John Ingman type, although some stocks of this latter germinated to a seed. It was very instructive also to note the superiority of stocks from gardens where the seeds had undoubtedly developed under the very best cultural conditions, and so long as cultivators continue to work the soil deeply, encourage good growth in the early stages, and apply plenty of phosphates to aid seed production, we shall always, as now, produce seed that will give the most vigorous plants."

HARP OF SWEET PEAS.
Arranged by Mr. H. A. Fox, Wellington, New Zealand.
(From "The Sweet Pea Annual," 1908).

MY GARDEN DIARY, 1908.

(Sutton and Sons, Reading.) Price 1s.

A dainty publication, equally suitable for the drawing-room and the garden office, combining as it does elegance with usefulness. Reminders of work to be done are given for each month, with notes on the changes of the moon, the rising and setting of the sun, the weather averages, and there is also space for memoranda. In addition there are at the end of the book concise notes on vegetables and selections of annual flowers.

A SIMPLE METHOD OF BOOK-KEEPING.

By H. W. Kersey. (Headley Brothers, Ashford and London.) Price 1s. 6d.

The object of this book is to provide a simple method of book-keeping which will give farmers and market gardeners a thorough knowledge of their financial position. The author, who is an expert in book-keeping, has been eminently successful in divising a method that is at once simple and efficient, and we can strongly recommend it to those who are desirous of keeping their accounts in a really satisfactory manner without the difficulties associated with keeping them by double entry.

THE "GARDENING WORLD" POCKET DIARY, 1908.

(Maclaren and Sons, 37 and 38, Shoe Lane, E.C.) Price 1s.

A handy diary for the pocket, in which much information relating to horticulture is given in a compact and readily accessible form. The diary pages are so arranged as to allow two pages to the week, and consequently provides as much space as could well be desired in a book to be carried in the pocket.

ELEMENTARY SCHOOL GARDENS.

Elementary school gardens are being created and developed in so many parts of the country, and with such great success, that we need offer no apology for publishing the following excellent and instructive report on these gardens, as they exist in Essex (1906-7), by **Mr. A. F. Butler, His Majesty's Inspector**:

The 42 school gardens in Essex were carefully inspected during the late spring and the summer of 1907, and, speaking generally, the work seen deserves much praise. Gardening is a subject which should have a foremost place in the curriculum of an elementary school where circumstances admit of its introduction. It is eminently practical, and provides both manual and mental training; it arouses children's interest in Nature, and encourages them to observe accurately.

Experience shows that the efficient teaching of gardening causes no deterioration in the general school-work. On the contrary, it is found to induce a more intelligent interest in the ordinary school subjects by showing their practical utility in the processes of everyday life. In order that gardening may occupy its proper place in the school course it is essential that the educational aim should be paramount, and the pecuniary value of the produce or the rearing of exhibition crops of secondary importance. The main object is not to train boys to be professional gardeners.

The subjects with which it can be profitably correlated are composition, mensuration, and arithmetic, Nature study and drawing. The scholars can describe the various operations in which they have been engaged. They can realise the use of mensuration and arithmetic in such exercises as measuring the garden and its plots; calculating the amount of soil displaced, weighing or measuring and estimating the value of the produce, and in keeping simple accounts showing the profit or loss on each plot and on the garden as a whole. They can study Nature in their gardens, and take notes of what they observe. These notes can be illustrated by drawings from the actual specimens. The children would thus be taught to see accurately, and these studies from Nature might with advantage take the place of the second-hand drawings from flat copies which are now so prevalent in the schools. The mending of broken tool handles, together with the preparation of wooden labels, etc., as done at the Purfleet Council School, enables the boys to become handy with the common carpentering tools.

Apart from its general educational value, horticultural knowledge is itself of much practical benefit to a rural population. The same principles are involved in cultivating crops in the garden as on the farm. An interesting illustration of the value of school gardening is seen at Roydon, where the school gardens, which form part of the village allotments, have for some years been a special feature. This year seven old boys who learnt their gardening at school are holders of allotments, and these are amongst the best cultivated. The allotment holders generally are said to take an interest in the school gardens and their youthful workers.

For some years a horticultural expert has been employed on the Essex County Staff, and classes for teachers have been conducted at Chelmsford and elsewhere. Thus a considerable extension of school gardening should take place in the near future, although in some quarters it is urged that suitable land near the schools cannot be obtained. A greater difficulty, however, is that arising out of the present staffing of the schools, which is often such that the head teacher cannot leave the schoolroom, and undoubtedly the best person to carry on this work is one of the school teachers, if he is interested in the subject and is a practical gardener. The employment of working gardeners is not entirely satisfactory unless a capable teacher is present for disciplinary purposes, and for keeping the theoretical class-instruction in touch with the practical operations of the garden. At Halstead, however, the school gardening is taught by a visiting "woman gardener," whose education, disciplinary powers, and special horticultural training enable her to carry on the work most successfully.

Of the 42 gardens in Essex, 33 are worked by the school teachers alone. In the other nine cases visiting gardeners are employed, two of whom have been specially trained in the Essex County Gardens. Several of the teachers also possess special qualifications, having attended the Horticultural Training Classes at Chelmsford, as well as being good practical gardeners. In four cases the subject is taken by women with much success, and it is important to note this now that the number of masters is gradually diminishing.

School gardening in Essex may unhesitatingly be pronounced a practical success, both teachers and scholars having entered heartily into the work. The different gardening operations have been well carried out; habits of tidiness, industry, and attention to details have generally been inculcated; and the crops have been satisfactory as to kind and quality.

Those who have had no previous experience in this matter, have been surprised at the keenness of the boys in the work, and at their unremitting attention to the gardens in their spare moments. In mixed schools the older girls have often shown a most appreciative interest in the plots, and have become critical as to their merits and defects. In some places the girls have been encouraged to form flower-beds and borders, which beautify the school surroundings, and it is hoped that this, together with window gardening, may become general in the county. It should be mentioned, also, that at a few schools the girls share in the theoretical instruction, and even assist in the gardening operations.

Alresford School provides a good illustration of successful gardening taught by a mistress under great difficulties, and here some commendable work is done in Nature study, the records of observations and the drawings of natural specimens being very good. At Great Braxted, too, the practical operations have been well taught by the mistress, and the crops have been good. At Roydon and Wakes Colne the use of a microscope and lenses for closer examination and observation of natural specimens is a feature much to be commended. The use and management of a "cold frame" have formed part of the practical instruction in a few cases, and might well become more general. A further development may be noted in connection with the school at Noak Hill, where the master has erected a greenhouse with suitable heating arrangements, and excellent use has been made of this.

The weakest point in connection with the gardening generally has been in its insufficient correlation with general school-work, and especially in—

(a) the keeping of simple accounts;
(b) the recording of operations and observations;
(c) the drawing of natural specimens.

Each boy should have a special note-book for this subject, and should keep exact records of his operations, experiments, and observations.

The plan of dividing the garden into plots, and, after reserving one or more of these for experimental and combined work, entrusting each of the rest to the care of one boy, or to a couple of boys, has been generally adopted. This certainly seems to be the best system. Where two boys share a plot, it is advisable, so far as is possible, to place a beginner with an experienced boy. The plots vary in size at the different schools, but the best results are obtained where one boy is held responsible for as large a plot as is possible and practicable. At Purfleet, for instance, each boy has a plot 30ft. by 18ft., and the master considers it "just as important that each boy should have a plot to himself as it is that he should have his own separate exercise book for school-work." The large experimental plot at this school is well stocked with trees and herbs, and thus an opportunity is provided for good practice in pruning, grafting, budding, and propagation by division. In many cases the common plot has not been made of sufficient value, but, to some extent, this may be due to the fact that several of the gardens have only been recently established.

At a few schools the plot system has not been adopted, in one case at least from choice, and in others for convenience and economy of space.

Land for the school gardens has been provided in three ways:

(1) by hiring or purchasing a piece especially for the purpose;
(2) by renting some of the village allotments;
(3) by using the teachers' gardens,

and in nearly every case the site is in close proximity to the school—a decided advantage.

The tools provided are, as a rule, adequate and suitable. It would be an advantage, however, if one set of tools were supplied for each plot, and more suitable accommodation provided for their storage at some of the schools. As the care and uses of tools are matters of importance in gardening instruction, it is advisable that each boy should be made responsible for one or more tools, and this can best be done where there is a special tool-shed with places labelled or numbered for each boy's tools.

The cost of seeds, manure, etc., has been met by the local education authority in some 30 of the 42 schools. In one case the boys have provided seeds, and in the remaining cases the head teachers have met the outlay. The most satisfactory plan seems to be for the local education authority to defray all expenses, and for the produce to be sold to recoup the outlay as far as practicable. But the sale of garden produce in country districts, where each house has its own garden, is not possible, and in such cases the produce is either taken by the boys or the teachers, or shared between them.

The schemes of work drawn up by the several teachers for the approval of the Board of Education were, in the main, satisfactory, and, in some cases, they gave evidence of most thoughtful preparation. Speaking generally, however, they were somewhat wanting in fullness, and did not sufficiently indicate the educational character of the instruction, the seasonal operations to be performed, and the general arrangements and equipment. These are matters applicable to all school gardening, and they might well be incorporated in the general county scheme without in any way discouraging the originality or the individuality of the teachers.

Each scheme should indicate clearly the scope and character of the proposed work, and show the general arrangements and equipment for carrying it out. Such a scheme would state:

(1) The dimensions of the garden, the number of plots (if any) into which it is divided, with the size of each plot, and whether the boys work singly, in pairs, or in co-operation.
(2) The use to be made of the common plot.
(3) The name of the teacher or teachers, with special qualifications (if any).
(4) The nature of the crops to be grown, how the seed is provided, and the manner of disposing of the produce.
(5) The seasonal operations to be performed, e.g.:—
    (a) Digging, double digging, trenching, ridging.
    (b) Manuring.
    (c) Mulching.
    (d) Seed sowing, planting and transplanting.
    (e) Gathering or raising of crops.
    (f) Pruning, grafting, budding, etc.
    (g) Utilisation and disposal of garden refuse.
(6) The chief points of the theoretical class instructions, e.g.:—
    (a) Nature of soils and suitability for different crops.
    (b) Manures and their special qualities.
    (c) Plants, their food, etc.
    (d) Garden pests and methods of eradication.
    (e) Rotation and succession of crops.

  (f) Climatic influences on soils and crops.
  (g) Economy of space in planting and cropping.
  (h) Care and use of tools.
  (i) Methods of storing produce.
(7) The method and extent of correlating gardening with ordinary school-work, e.g.:—
  (a) Drawing to scale—drawing of natural specimens.
  (b) Nature Study—plants, etc., used for illustration of lessons and for inducing observation, accompanied by note-taking and illustrative sketches.
  (c) Mensuration and Arithmetic—keeping of accounts.
  (d) Composition—exercises on operations, observations, and deductions.
(8) The character of the records and notes to be kept by the teacher and by the scholars.
(9) The general equipment, e.g.:—Tools, shed, cold-frame, etc.

EARLY CAULIFLOWERS.

Cauliflowers occupy an important place among vegetables, and their production in quantity over as long a period as possible will necessitate considerable attention and care in sowing and growing on the several batches of plants that will be necessary to form the successional crops. What we are specially interested in at this season is the earliest crop to give the first heads. There are two ways in treating the plants. The older plan of providing the early supply was to sow seed about September and winter the young plants in frames till March or April, according to the conditions of the weather, when they were planted out in their permanent quarters. Through change of circumstances this is not practised to the same extent now, and more reliance is placed upon a sowing this month.

Sowing Seed.

First Crop, Early Snowball, and Early London are good varieties, but I prefer the two first-named, with Early London to follow. Somewhat shallow pans or boxes are suitable for this sowing if filled with an open gritty compost. One of the pitfalls for beginners is that of sowing the seed too thickly, which results in weakly plants that are particularly liable to damp off near the soil and become worthless. Sow thinly, and place the plants from the time the seed has germinated in the lightest position near the roof glass in a temperature not exceeding 45 to 50 degrees. To ensure sturdy growth from the commencement water must be given carefully.

When the rough leaves have well commenced to form the seedlings will be ready for pricking out. If a carefully prepared mild hotbed can be made up of leaves and litter, on which a frame can be placed, and the hotbed covered with a layer of rather sandy, open soil, here the plants should be pricked out at six inches apart, and they will make rapid progress. If conveniences exist for another plantation in a pit, over another mild hotbed, one may slowly force on a batch to give the first heads; or if grown on steadily, with plenty of air on all favourable occasions, and gradually inured to the weather, they will form the first plantation outside in March or April. Smaller plants from this, or slightly later sowing, may be also pricked out at the same distance apart in a bed of sandy soil placed on a cool base in a cool frame; after becoming established they must be allowed plenty of air on fine days. This will probably be the most satisfactory plantation.

Site and Soil.

An elevated south border is without doubt the best possible position for the first planting, because here one avoids atmospheric moisture during frosty nights, and obtains the fullest benefit from the sun on bright days. On light soils especially deep digging or trenching, with plenty of manure incorporated, is essential for cauliflowers, but with heavy land less manure may be required, but deep cultivation is of the greatest advantage here for most of the brassicas. Coarse heads are not required, but a great difference exists between a thin poor flower head and one that has been properly grown.

Planting Out.

Discretion is required at this stage as to how and when to plant out, as a severe check to the plant will certainly bring about premature buttoning, and probably the heads will be so small as to be useless. Failure of this kind is caused in some cases by the plants being insufficiently hardened before being exposed to the open, so that it is best to have the lights entirely removed for a time before planting that the tissues of the plants be consolidated.

The time to plant must be absolutely ruled by the conditions of the weather, soil, and district. Here it is a great risk to plant until the end of March or beginning of April, even with careful night protection of spruce boughs, which we consider the best means of warding off cold winds and frost. Failing this laurel boughs or 32-sized pots are useful. A distance of two feet from row to row and eighteen inches from plant to plant for this permanent planting is ample to allow of full development.

The plants, previous to being removed, should receive a thorough soaking of water to settle the soil, and be afterwards lifted with a trowel to secure a ball of earth to each one; they should be conveyed to their permanent positions in trays with the least possible shaking, and planted firmly, without unduly crushing or damaging the roots. Considering the amount of moisture in the soil at this time of year a light watering only will be required. Afterwards the amount of the rainfall must determine the watering necessary.

C. Flack.

Cholmondely Castle Gardens.

Mowing Lawns.—The mild autumn caused the grass to grow on lawns unusually late in the year, and the latter weeks of 1907 were so wet that it was impossible to get the lawn mower to work. This means that the grass is now becoming very untidy, and an early opportunity should be taken of having it cut. Worm-casts are the greatest trouble at this season, as not only do they choke up the machine in wet weather, but they harden in frost, and so prevent mowing being done then. The thing is to keep them scattered with a besom or rolled down, then should a nice frosty period supervene, the machine can be run over the grass with ease.—E. J. K.

The White Jasmine on a North Wall.—The white jasmine is generally looked upon as being a little tender, and while its yellow-flowered sister is often recommended for and found doing well on a north wall, it cannot be said that the white finds equal favour for such a position among gardeners in general. But that it will thrive excellently on a north wall, that is the north wall of a dwelling-house, I had ample demonstration last summer, when I saw a specimen 20ft. high and laden with bunches of its fragrant white blossoms. The house, too, was on an exposed hillside, so that the jasmine had no shelter from the north winds.—E. J. K.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

SEED SOWING.—In gardens where hybridisation is practised—and there are but few places now where orchids are grown without home-raised seedlings from the material at hand for cross-fertilisation purposes—one must consider the subject of seed sowing. For members of the cattleya family, epidendrums, dendrobiums, and other epiphytal orchids that ripened their seed vessels during the closing months of last year, advantage is obtained by deferring seed sowing until the turn of the days; better light facilitates the work, and fewer disadvantages are experienced with small seedlings.

METHODS.—There are several methods of sowing orchid seed. The one in general practice for these epiphytes is to fill a four-inch pot to about one-half its depth with broken crocks or chopped bracken roots, and over this is placed a layer of ordinary potting compost. Select a piece of bookbinder's linen, the No. 5 roof shading providing it is new and clean, or any coarse-grained cotton or silk material. In this roll tightly, so as to form a ball, some clean chopped sphagnum moss, press this into the top of the pot, and pack a little more chopped sphagnum firmly around the edges so as to keep the ball in position; thoroughly wet the compost with tepid water, and as soon as this has drained the seed may be thinly and evenly sown on the surface. Place the pots in a moist propagating case, with an even temperature of from 70 to 75 degrees; if the seed is good it should show signs of germination in a few days. As the seed requires more moisture care must be observed to give it in such a manner that the seeds do not get washed or floated from their position.

WOOD BLOCKS.—A very good method is to obtain round dry deals, such as thin ends of scaffold poles; roughly saw these asunder, so that the grain of the wood may be left rough. After fitting them to suitable sized pots, the wood should be put into the rainwater tank for a few days to become well soaked. When ready for sowing, fix them into the pots filled with drainage, and fill any marginal space with finely chopped sphagnum. This is a very good method where the facilities of a propagating case are not available, for although the seed may be longer in germinating, the wood better resists fungoid attacks than does linen. Place the blocks, as soon as seed has been sown, in a warm, moist position where they may have every advantage of the available light.

CYPRIPEDIUMS, CALANTHES, and other terrestrial orchids are best suited by having their seeds sown on the surface material of a selected plant of the kind to which they belong. The seed should be sown thinly and on several pots, if possible. I have sown seed on a number of pots, and in several instances the seed has only satisfactorily germinated on the surface of one, a fact that is difficult to account for, as all had been treated precisely the same.

ODONTOGLOSSUMS, with us, germinate more readily than any other class of orchids. There was only a small portion of seed sown from each of the seed pods last year, and we have more plants than we can well find room for. I do not hesitate to sow odontoglossum seeds at any season; they are sown whenever pods ripen. The seeds are sown on the surface of pots containing plants of their own kind, and a surface selected that is practically free from moss and algæ growth, so that the seedlings may not become overgrown or choked. The ordinary potting compost of about equal portions of fibrous peat, broken leaves, and sphagnum is what they are sown on, and we find germination very rapid.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

EUCHARIS AMAZONICA.—Plants which have been flowering through the autumn are now showing signs of growth. Those desiring to increase their stock of plants should take advantage of the early season when potting is necessary. I have found that restriction of the roots to promote flowering is altogether unnecessary, and that, if practised to any extent, eventually proves detrimental to the health of the plants. A very successful system is to pot up one-half of the batch each spring when the largest specimens are divided into suitable sized ones, and the smaller plants potted separately. Our potting compost consists of two parts loam, one of peat, and one of dried sheep manure, with charcoal and coarse sand added. When potting eucharis bulbs it is advisable to dispense with the use of a potting stick, and press firmly but carefully around the roots. After potting plunge the pots into bottom heat if possible, and maintain a moist atmosphere by damping and syringing. The plants will not require much water until the leaves have considerably developed. Bulbs which have been infested with eucharis mite should have the whole of the soil removed from their roots and both bulbs and roots thoroughly washed with a solution of carbolic or paraffin soap.

EUPHORBIA JACQUINIÆFLORA. —Plants, as they pass out of bloom, should be placed on a shelf near the glass in order to produce a stock of cuttings for early propagation. If attention is given the stock plants by affording them a light position in the stove, the cuttings are not so liable to damp.

GENERAL REMARKS.—A general overhauling and thorough cleansing of stove plants is always required in early spring previous to starting the plants into growth. If this work is done thoroughly it will save a great deal of labour later in the season. All creepers should be removed from the roof, carefully pruned, and tied up again.

GLOXINIAS.—The present time is a suitable one for sowing seeds of gloxinias or other stove subjects. For this purpose shallow pans, which are clean, and well drained with broken crocks, are preferable. Prepare a finely sifted compost of loam, leaf-soil, peat, and silver sand in equal parts. The soil should be moistened, and the seeds sown thinly and regularly over the surface; cover very lightly with fine sand, and over each pan place a sheet of glass.—John Donoghue, Bardon Hill Gardens.

FRUITS UNDER GLASS.

PINES.—Plants that were late in throwing up their fruit last autumn, and have been kept in a somewhat lower temperature may now be given fresh plunging material; keep this at about 85 degrees, and then they will soon start swelling again, and, though small, will provide a good early supply of fruit. They may be top-dressed with some fresh loam and bonemeal. White scale very often affects these, and should be cleaned off the leaves before it spreads on to the fruit. The pit or house for successional plants should be cleaned, the walls scraped and whitewashed down, and the corners and crevices well syringed with paraffin and hot water to dislodge all insects. Fill the bed with clean leaves, and plunge the plants in these when the temperature ranges from 70 to 75 degrees, with a top heat of 60 degrees. Damp down the walls and all dry places, and on bright days a slight damping overhead may be given with tepid water. Remove any suckers that appear, and, if required, pot them in small pots and plunge in a slight bottom heat.

STRAWBERRIES.—Those in flower will require to be artificially fertilised by means of a very soft brush, taking care that both flowers and brush are dry; when set reduce the fruits to five or six of the best to each pot. More heat may soon be given, with air on all favourable occasions, but cold draughts should not reach the plants or mildew will appear. Place another batch in a cool house or pit to keep up a succession, and allow for a few blind plants.

TOMATOES.—The winter-fruiting plants will still be yielding a few fruits, and should be given every encouragement; top-dress them with a good open soil and a little artificial manure, and keep all decayed leaves removed. Young growths will appear and flowers may be set, but it is not advisable to rely on these for a crop. Lye's Early Prolific set fruits in December, but these did not come to any useful size. Young shoots of this variety struck last December are now potted into 54-sized pots, stood on a bed of ashes in a temperature of 60 to 65 degrees; these will be shifted on again as soon as they are sufficiently advanced. At this time of the year such plants are best without a large bulk of soil, hence small shifts are best. The batch should be fumigated once a week to keep down white-fly. Seedlings raised the first week in January will be ready for potting singly into small pots; place them on a warm shelf near the glass away from the draught.

POT VINES.—As the shoots become strong enough they may be only slightly pulled down to the wire or the sun will draw them back and break off the shoot; stopping may take place two or three leaves from the bunch, but the bunches should be well advanced before this is done; give air on all favourable occasions, closing the house with sunheat when possible. When the vines are in flower reduce the moisture, and, if possible, admit a little air to the house till they are set; if the weather is at all favourable no artificial setting will be required.

ORCHARD HOUSE.—If the trees are not too tall for the house they are best not plunged until the fruits have set, as watering can be done more carefully without it. Syringe the trees twice a day, and close up with all sunheat when possible. Apricots will probably be the first to open their flowers, and they should be placed at the coolest end of the house. If there are too many flower buds showing some of them may be removed, and a slight fumigating before they expand will be beneficial.—A. B. Wadds, Paddockhurst Gardens.

THE KITCHEN GARDEN.

HOTBEDS.—Where these have not already been made, they should now have immediate attention; they are most useful for forwarding early supplies of vegetables, and serviceable for assisting other crops. The making of a hotbed requires some practical knowledge, for if built in a haphazard manner, the heat will not be lasting. Thoroughly mix together three-parts of fresh leaves with one of long litter, and tread them firmly down as the work of building the bed proceeds. When portable frames are to be used the beds should be fully half a yard wider on each side and ends than the frames to allow for relining as the heat declines.

EARLY POTATOES.—Another batch may be planted in pits or frames, slightly heated either by fermenting material or pipes. The most suitable varieties for this work are Sharpe's Victor and Ringleader, as they are both dwarf and produce fair crops of good flavoured produce. Loam of a light nature, mixed with old potting shed soil, and some lime rubble, with a sprinkling of bonemeal, makes up a good compost.

PEAS.—It is generally one of the chief aims of the gardener to secure a few dishes of peas as early as possible. To accomplish this a batch should be sown in 8-in. pots at once, using an early dwarf variety, such as Little Marvel, or Carter's Early Forcing, and growing them in the cool fruit houses well up to the glass. For succession to these, Exonian and Gradus should be sown in 4½in. pots, or on turves about five or six inches wide, placed on boards, covering them over with an inch of soil. Put these in mild heat until they are ready for hardening off. If the weather is favourable, and the soil is in a fit state for working, a few short rows should be sown on a warm border outside, choosing a round seeded variety at this date to make certain of the seed not rotting through excessive moisture.

SPINACH.—If a few rows of spinach are sown between the peas they will come on very well, especially if the soil has been well worked.

CARROTS.—Where plenty of frames are at command, one or two might be utilised by half-filling them with fresh leaves, and covering these over to a depth of six inches with any light soil, and sowing Inimitable Forcing and Paris Market, which are two good early carrots. This may be followed by Early Short Horn and Nantes.

ONIONS.—Where large well-ripened bulbs are required, it is necessary to sow the main crop in boxes, in some good rich soil, placing these in a peach house or vinery that has been started. Ailsa Craig and Record are useful varieties for the purpose, the latter makes a heavy and finely-shaped bulb, which keeps well. As soon as germination takes place, let the plants have all the light possible, and be placed well up to the glass. When they are large enough to handle they should be pricked out in other boxes, and carefully hardened off before planting outside in April.

MUSHROOMS. — Continue to collect the manure each day, and place in an open shed, keeping it well turned to get rid of the rank steam. When enough has been secured, it should be made up into a bed in the mushroom house, making it very firm, and when the heat has declined to about 89 deg. the spawn should be inserted ten or twelve inches apart in rows, and about two inches deep, and the bed covered with an inch and a-half of good soil. Follow this with a layer of straw, and keep up a temperature of 55 deg.

VARIOUS.—Any vacant plots should be trenched without delay, and exposed to the weather. Radishes should now be sown in pits or frames; Wood's Early Frame and French Breakfast are good reliable sorts; keep them well supplied with water while growing. Mustard and cress must be sown every few days in heat, and endive be planted out in the mushroom house at intervals for blanching.—T. W. Birkenshaw, Hatley Park Gardens, Sandy.

Prunus japonica flore plena.—Where hardy shrubs are forced into bloom for the embellishment of the greenhouse during the early months of the year, this delightful little member of the plum family (which, by the way, is often known as Prunus sinensis), occupies a foremost position among even the most select. It forms a neat bushy specimen, and when at its best the slender, rather upright shoots are studded for some distance with large double blossoms, suggesting those of a double-flowered cherry. There are two forms, one in which the flowers are pure white, and the other in which they have a pinkish tinge. This latter feature is more noticed in the bud state and just as the flowers are expanded than it is afterwards. Another point in its favour is that it retains its beauty when forced longer than many other shrubs, and a succession of blossoms is kept up for some time. This prunus may be grown altogether in pots, and under such treatment it can be depended upon to flower year after year, added to which, plants that are continually forced flower earlier than those so treated for the first time. In the case of those it is intended to keep in pots they should as soon as the blossoms are over, have the flowering shoots cut back to within a couple of inches or so of the base. They must still be kept under glass and encouraged to make good vigorous shoots. Then when all danger from frosts is over the plants can be plunged in a sunny spot out of doors, where the wood will be well ripened. In obtaining plants of this prunus care must be taken to see that they are on their own roots, as they are often budded or grafted on to the sloe, and the suckers from the stock are always a nuisance.—W. T.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at ninepence per line, the minimum charge being Five Shillings. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Gardeners' Royal Benevolent Institution.

There was a good attendance at the annual meeting held at Simpson's, Strand, W.C., on Thursday, January 23, when Mr. Harry J. Veitch presided. Those present included: Messrs. A. W. Sutton, G. J. Ingram, G. Monro, T. Morris, G. Wythes, O. Thomas, G. Gordon, J. Willard, W. Poupart, A. W. Paul, Rochford, W. Howe, J. McIndoe, etc., etc.

The following report and balance-sheet were presented:

COMMITTEE'S REPORT FOR 1907.

The committee, in submitting their annual report, together with a statement of receipts and expenditure (as certified by the auditors) for the year 1907, again have the pleasure of congratulating the subscribers and donors to the institution on its continued success.

At no former period in the sixty-eight years of its existence has so much been done in the way of affording permanent and temporary assistance to the unfortunate members of the horticultural community—gardeners, market growers, nurserymen, etc., and the widows of such—as during the past year. Over £4,000 has been disbursed in permanent aid alone. That this happy condition has obtained is a matter for thankfulness, and the committee feel it is also an encouragement to the subscribers and others whose generous liberality has enabled them to carry on the work.

At the beginning of 1907 there were 227 pensioners on the funds—123 men and 104 widows—receiving annuities of £20 and £16 per annum respectively for life. During the year twenty have died, one man has been removed to an infirmary under medical orders; another, a widow, to an asylum owing to her mental condition, and another has left England for America to reside with her son. Of the men who died, three left widows, whose circumstances being such as to render them eligible, have been placed on the funds without election to receive the widows' allowance of £16 a year each for life, under Rule iii. 13. The committee now recommend an election from an approved list of fifty-two candidates, to fill the vacancies created.

The "Victorian Era Fund," and the "Good Samaritan Fund" still prove a source of much benefit and comfort. From the former fund nearly £200 has been distributed amongst the unsuccessful candidates at the last election who had formerly been subscribers, in terms proportionate to the length of time they had subscribed; and from the latter fund £106 has been given in small amounts as temporary relief to numerous applicants—whether subscribers or not—whose cases were of a most distressing and pathetic nature. The committee again beg to draw attention to the value and utility of these two funds; the one helps the candidate awaiting election, whilst the other bestows temporary help in cases of emergency. As the income only from these funds is available, special contributions ear-marked for either of them will be warmly welcomed.

The annual festival dinner which took place at the Whitehall Rooms of the Hotel Metropole on June 26 last, under the presidency of the Hon. Walter Rothschild, M.P. (trustee), was most successful, and resulted in a substantial sum being raised towards carrying on the work. The committee desire to place on record their gratitude and indebtedness to the chairman for his earnest advocacy of the claims of the charity, and for his generous contribution to the funds. They also take this opportunity to express their sincere thanks to those gentlemen who acted as stewards or collectors; to the contributors of flowers; to the horticultural Press for their gratuitous and invaluable help; to Mr. James Hudson, V.M.H., for superintending the decorations; and to other friends throughout the country who in any way, directly or indirectly, contributed to the gratifying result attained. Grateful thanks are likewise tendered to the Right Hon. Mary Countess of Ilchester, for again allowing her beautiful gardens at Holland House to be opened to the public on the occasion of the great summer flower show of the Royal Horticultural Society, part of the proceeds obtained therefrom being handed to the institution; also to the Right Hon. Earl Beauchamp (Madresfield Court), and Sir Frank Crisp (Friar Park) for similar kindness for the same object.

To the "Geo. Munro" Concert Committee they offer their acknowledgment for again contributing to the funds. Sincere thanks are likewise accorded to N. N. Sherwood, Esq. (trustee), for his gift of £20 to the unsuccessful candidates at the last election; and to Arthur W. Sutton, Esq. (member of committee), for kindly supplying a similar amount for a year's allowance in support of an incurably paralysed candidate. Very gratefully do the committee also acknowledge the services rendered by the hon. treasurers and hon. secretaries of the several auxiliaries which continue to be a source of strength and support, not only in obtaining additional financial aid, but in maintaining, as well as creating interest in, the operations of the charity.

It is with great pleasure the committee have to announce that the Right Hon. Lord Aldenham will preside at the sixty-ninth anniversary festival dinner in aid of the funds on Wednesday, June 24 next, at the Whitehall Rooms, Hotel Metropole. They hope his Lordship will be warmly supported.

The committee, unfortunately, have again to refer to the large number of losses by death amongst the friends and supporters of the institution they have sustained during the past year. They would especially mention the Marquis of Bristol and Maxwell T. Masters, M.D., F.R.S., both of whom were vice-presidents for over forty years, and took a lively interest in the institution. Dr. Masters being always ready to help forward the work. Among others who have passed away are Sir Alex. J. Arbuthnot, chairman of committee for a short time some years ago; Mr. James H. Veitch, also formerly a member of committee; and Lord Battersea; the Hon. Mark Rolle, Sir Michael Foster, Baroness Burdett Coutts, Mr. J. Hill White, one of the founders and hon. treasurer of the Worcester Auxiliary, and Mr. R. B. Cater, of the Bristol and Bath Auxiliary.

With much gratitude the committee acknowledge the practical aid and sympathetic help afforded them in their work, and they now very earnestly appeal to every well-wisher of this National (unsectarian) Horticultural Charity for further exertions and interest on its behalf, so that the beneficial work which has been carried on with such signal success for the poor and needy for so many years may continue to be maintained.—**Harry J. Veitch**, treasurer and chairman of committee; **George J. Ingram**, secretary.

RECEIPTS AND EXPENDITURE FOR 1907.

RECEIPTS.

To Balance	£1,001 13 2
Amount on deposit	3,580 0 0
Annual subscriptions	1,464 17 6
Donations at festival dinner	2,796 14 3
Legacy, the late H. Aiton, Esq.	10 0 0
Grant from Exors. Edward Poole Estate	64 9 5
Return of Income Tax	42 19 8
Dividends	937 15 3
Sale of waste paper	0 8 6
	£9,898 17 9

EXPENDITURE.

By Pensions and gratuities, including Mr. Sherwood's and Mr. Sutton's gifts	£4,033 14 9
Expenses annual meeting and election	9 19 0
Rent, firing, salaries of Secretary and Clerk	566 18 5
Printing and stationery	88 15 1
Expenses festival dinner	53 16 11
Postages, travelling expenses, insurance, etc.	72 4 8
Investment in India Three per Cent. of grant from "Edward Poole Estate"	64 9 5
Placed on deposit	3,880 0 0
Balance with Treasurer and Secretary	1,129 9 6
	£9,898 17 9

In accordance with the rules of the Gardeners' Royal Benevolent Institution, we certify that all our requirements as auditors have been complied with, and we report to the subscribers that we have compared the books, together with the bankers' certificate of securities deposited with them, and that the balance-sheet is a true and correct account of same. We also wish to add that we find the books well kept.

		£373 17 5
		£373 17 5

The Chairman moved the adoption of the report and financial statement, remarking that it was a full report and a satisfactory one. He was a little anxious for the future because their losses by death had been severe. Dr. Masters had passed from them since the previous annual meeting. But he hoped others would come forward to fill the places rendered vacant. They would that afternoon proceed to elect eighteen pensioners to the benefits of the fund, and he was glad to announce that Mr. N. N. Sherwood, V.M.H., had given £25 to be distributed among the unelected candidates—an increase of £5 on his gift in 1907. During the year just ended the institution had distributed £4,334 16s. 9d. The motion was duly seconded, and carried.

Mr. Arthur W. Sutton, V.M.H., moved the re-election of Mr. Harry J. Veitch as treasurer, and eulogised the services he had so long and ably rendered. He also said that, in view of recent enactments, members of the trade who wished to show they were well disposed towards gardeners, should show their good feeling by subscribing liberally towards the gardening charities. Mr. Denning seconded the motion, which was carried and duly acknowledged by Mr. Veitch, who pointed out that 355 votes had been lost that day on a total of 48 papers, owing to the latter being unsigned.

Mr. G. Monro, V.M.H., proposed the re-election of Mr. E. J. Ingram as secretary, and this was seconded by Mr. E. Wythes, V.M.H., both of whom warmly praised Mr. Ingram's work. On the motion of Messrs. C. H. Curtis and W. Poupart, the retiring members of committee were all re-elected. The auditors, Messrs. T. Swift, B. J. Monro, and J. Willard, were re-elected, on the motion of Messrs. O. Thomas and J. McIndoe, and heartily thanked for services rendered.

Messrs. B. J. Monro and E. White were appointed scrutineers of the ballot, and the chairman, in adjourning the meeting for the declaration of the poll, announced that Mr. A. W. Sutton had kindly provided a pension for the year for a selected non-elected candidate.

The poll was declared soon after 4.30 p.m., when it was shown that the following had been elected: James Mack (3,671 votes), W. Cookson (3,455), Wm. Swanborough (3,307), George H. Green (3,073), Jas. Chesher (2,972), Wm. Edwards (2,797), Robt. McAdam (2,788), Mary Manderson (2,633), Euphemia Chinging (2,543), John Stanton (2,535), Nehemiah Blandford (2,498), George Little (2,496), Thos. J. Foote (2,481), Ann J. Solman (2,452), Wm. Pooley (2,426), Chas. Kinns (2,360), Robt. Maher (2,357), Alex. Clark (2,338), and Wm. Moore (2,270). Two others were voted on in accordance with the rule, and these were Wm. Jones (1,957), and Susan Hale (1,561). The "Sutton" pensioner is Thos. Jones, and, as Mr. G. Monro kindly promised to provide a pension for one year, this was granted to Laura Stockwell, who only polled 106 votes.

Votes of thanks to the scrutineers and chairman concluded the proceedings.

FRIENDLY SUPPER.

During the evening about sixty friends of the institution joined at supper, under the very able presidency of of Mr. Martin H. F. Sutton, of Reading. Messrs. H. J. Veitch, E. White, Bilney, E. Sherwood, W. Sherwood, J. F. McLeod, G. Monro, P. C. M. Veitch, J. Monro, G. Paul, H. G. Cox, M. Veitch, J. G. Veitch, W. Howe, E. T. Cook, H. G. Cove, etc., etc., were present.

After the loyal toasts, the Chairman proposed "Our Institution—its Continued Prosperity," and did so briefly and admirably. He pointed out the national character of the charity and said it was worthy of the assistance of all connected with horticulture. Instead of declining after its "three-score years and ten"—it was now 69 years old. He hoped the institution would increase in usefulness and prosperity. Already £117,000 had been distributed, and the pensions had gone to all parts of the United Kingdom. What relief this assistance had brought it was impossible for one to fully realise. But, though glad of the past usefulness and present position, he urged all to do their best to make the future brighter and better. No one was more worthy of relief in times of need, for no other skilled labour was so poorly paid, and it required many years of patience to save enough to smooth the declining years. Mr. Sutton was heartily applauded for his remarks, and Mr. Harry J. Veitch who responded to the toast, heartily thanked the chairman for his presence and speech. He stated there were now 123 men and 104 women on the funds, and the annual pension list, together with assistance rendered the unsuccessful candidates from the Victorian Era and Good Samaritan Funds, now amounted to about £4,400 a year. He wondered sometimes whether if old age pensions became a state matter, whether the institution would cease, and what would become of their invested capital. They had lost many friends in 1907, including Dr. Masters, but they had many good friends, who were also very generous, notably Mr. N. N. Sherwood, Mr. A. W. Sutton, and Mr. G. Monro.

Mr. G. Paul proposed "The Committee, Honorary Officers, and County Friends," and to this toast Messrs. W. A. Bilney, E. White, and P. C. M. Veitch responded. "Our Chairman" was proposed by Mr. Edward Sherwood, and pleasingly acknowledged.

The music, kindly provided by Mr. M. H. F. Sutton, and supplied by the Westminster Singers, was unusually good; indeed, we cannot recall such an exquisite rendering of charming music at any previous function of a similar character we have attended.

Oxfordshire Chrysanthemum and Fruit Society.

This society recently held its forty-fourth annual meeting of subscribers at the New Inn Hotel, Oxford. Mr. Councillor Turrill presided over nearly thirty members. The annual report referred to an improvement in the specimen plants and groups for effect; cut blooms demonstrated a high standard, though there were fewer than in some seasons; the two hundred dishes of hardy fruit were regarded as a wonderful display in an uncertain season; and the vast array of collections and single dishes of vegetables proved the suitability of the district for producing high-class quality. The statement of accounts revealed the fact that, despite a large attendance (2,750 tickets being handed in), there was a loss of £3 7s. 9d. on the year's working, traceable to an increase of prize money. Harvey du Cros, Esq., M.P., was chosen president, and Mr. W. Greenaway, secretary (fortieth year). The next show is fixed for November 10.

Royal Horticultural Society.

JANUARY 28.

There was a fairly good display on the above date, and, as the weather was favourable the attendance was good. Orchids were a feature, and other leading displays were of primulas, cyclamens, shrubs, carnations, and potatoes.

FLORAL COMMITTEE.

Cyclamens were extensively shown by Messrs. Sutton and Sons, Reading, who make a speciality of these flowers. They had freely-flowered, well-grown plants of White Butterfly, Giant Salmon Pink, and a particularly good selection of superb fringed varieties in very many shades of colour, notably the white grounds with purple edges and tips. These made a most effective and interesting display. From the Guildford Hardy Plant Nursery came a collection of Alpine shrubs, notably heaths and veronicas, with a few berberis and rhododendrons. Messrs. H. B. May and Sons, Edmonton, had a most interesting exhibit of ferns, showing excellent examples of Davallia tenuifolia Veitchi, Platycerium stemmaria, Nephrolepis todeaoides, the charming Asplenium elegantulum, Nephrolepis Whitmani, etc. With these were elegant and bright dracænas, crotons, and aralias, and a fine strain of Primula obconica.

Messrs. Wm. Cutbush and Son, Highgate, N., had a large exhibit, in which early flowers, such as Adonis kikusaki, A. amurensis, Iris reticulata, I. histrio, Helleborus niger major, Jasminum nudiflorum, Hamamelis arborea, and heaths were noticeable. This firm also had Daphne indica, camellias, acacias, Erica Wilmoreana, and a collection of perpetual-flowering carnations, the latter including St. Louis, Enchantress, Glendale, My Maryland, Helen Goddard, Robert Craig, and Mrs. Burnett. The Misses Hopkins, Mere Gardens, Shepperton-on-Thames, exhibited a small collection of rockwork plants, and a fine basketful of hellebore flowers. Some very beautiful carnations were exhibited by Mr. H. Burnett, Guernsey, who showed fine stands of big blooms of Mrs. H. Burnett, Marmion, Enchantress, Robert Craig, Mikado, Winsor, Britannia, White Perfection, and Mrs. T. W. Lawson.

Primulas in variety and a collection of saxifragas, sedums, and other evergreen alpine plants, was submitted by Messrs. J. Peed and Son, West Norwood, S.E. Messrs. H. Cannell and Son, Swanley, set up some wonderful primulas; these were of the true florists' or Chinese type, and they carried flowers of unusual size and substance, though at this date there were not many on each plant. The group included a number of new seedlings, and the salmon and crimson shades were very pleasing. Messrs. John Waterer and Sons, Lim., Bagshot, Surrey, contributed a very handsome and interesting display of hollies, in both standard and bush forms. The yellow-berried holly was very fine, as were the specimens of Golden Queen, Lawsoniana, Silver Queen, Golden King, the uncommon Ilex latifolia, the Scotch Golden, Waterer's Golden, Milkmaid, and Moonshine, the latter a very distinct and effective variety.

Mr. G. Reuthe, Fox Hill, Keston, brought up early crocuses, adonis, berberis, hellebores, and hardy heaths, and cyclamen, etc. Some very interesting and effective shrubs were shown by Mr. L. R. Russell, Richmond, and the most attractive were Garrya elliptica with its tasselled spikes, Aucuba vera, full of berries, Eleagnus japonica aurea, Cupressus macrocarpa lutea, Buddleia asiatica, Eurya latifolia variegata, and euonymus.

The exhibit of perpetual-flowering carnations made by Messrs. Hugh Low and Co., Bush Hill Park, Enfield, was a very effective one. There were large vases of such popular varieties as White Perfection, Enchantress, Rose Pink Enchantress, Mrs. Burnett, Mikado, Britannia, Lady Bountiful, Robert Craig, and Cardinal. The same firm showed Euphorbia jacquiniæflora, some fine salmon-coloured cyclamens, and the sweet Daphne indica. Early flowers were contributed by Messrs. Barr and Sons, Covent Garden, and these were very pretty, and included crocuses, snowdrops, hyacinths, ericas, hellebores, etc.

Mrs. Sophia Miller, Moyleen, Marlow, showed several dozen water-colour drawings of flowers and garden scenes; the carnations, the hellebores, and the crinums appealed most to us. Paintings of various flowers, many of the studies being designs for tiles, etc., were shown by Miss Summer Jones, Wellesley Road, Chiswick. The carnation pictures were very good.

ORCHID COMMITTEE.

Some charming orchids were grouped by Messrs. Charlesworth and Co., Heaton, Bradford, and among the many good things we noted Lælio-cattleya Prospero, Cattleya Octave Odoin, L.-c. Andromeda, C. Enid, and Odontoglossums in variety. Mr. Hopkins, gardener to F. Wellesley, Esq., Westfield, Woking, brought forward Cypripedium Mr. F. Sander (A.M.), a bright and finely-formed hybrid; and C. Rajah, the latter a very bold cross between C. Io grande, and C. Swinburnei magnificum.

Some lovely odontoglossums were sent over by Messrs. Linden and Co., Brussels; O. crispum Jean Linden, with heavy red-brown markings on a finely-formed flower was splendid; O. Nottianum, O. exultum formosum, and O. Orphanum, the latter with a beautiful spike of ten flowers—were all of first-rate quality. Cypripedium Fairieanum Cookson's var. (A.M.), with very dark purple tips to the dorsal sepal, was shown by Mr. Chapman, gardener to N. C. Cookson, Esq., Oakwood, Wylam-on-Tyne. Mr. Alexander, orchid grower to Major Holford, Westonbirt, Gloucester, sent up the showy Golden Lælio-cattleya Goldfinch, Cattleya Cyril, and Cypripedium Bianca.

Numerous handsome cypripediums were shown by Messrs. James Veitch and Sons, Chelsea; there were specially good blooms of the C. villosum group, some good odontoglossums, Trichopilia suavis, and Brasso-cattleya Orpheus rosea, and the quaint Neobenthamia gracilis. Messrs. Hugh Low and Co., Bush Hill Park, Enfield, had a fine plant of Cypripedium aureum virginale in their group of orchids; around it were various cypripediums, Odontoglossum Rossi majus, Lælia anceps, etc.

Some beautifully-grown odontoglossums, chiefly white forms of O. crispum, were shown in quantity by Messrs. J. and A. McBean, Cooksbridge, Sussex, and the group was the most beautiful in the hall. The plants were grandly grown, and the spikes long and graceful. Epiphronitis Veitchi, and white forms of Lælia anceps were also shown equally well by these famous growers. Some freely-flowered specimens of Cattleya Percivaliana were shown by Messrs. Heath and Son, Cheltenham, who also had a goodly set of cypripediums, such as C. Leeanum, C. villosum, and C. insigne varieties.

Messrs. Cypher and Sons, Cheltenham, contributed a fine and interesting collection of cypripediums, with a few odontoglossums and a large Cymbidium Uraniarum. Among the cypripediums we noted C. Leeanum viginalis, C. Fairieanum, C. Almos, C. nitens F. F. Smith, C. aureum virginale, and C. Sallieri Hyeanum. Messrs. J. W. Moore and Co., Lim., Rawdon, Leeds, exhibited a small group of orchids in which were Odontoglossum Harryano-crispum, O. crispum, a fine form of Lycaste Skinneri, and numerous good cypripediums.

Well-grown and finely-flowered plants of Cypripedium insigne Sanderæ, C. Euryades, C. Leeanum, C. villosum, C. Minos, etc., were contributed by Mr. Balmforth, gardener to F. Mentieth Ogilvie, Esq., The Shrubbery, Oxford. From Messrs. Armstrong and Brown, Tunbridge Wells, came some good forms of Odontoglossum crispum, including a very shapely pure white variety; Sophronitis grandiflora, Cypripedium Helen II., Cymbidium Woodhamianum, and Brasso-cattleya Mdme. Hye, were other prominent orchids in this group. Mr. Bound, gardener to Sir J. Colman, Gatton Park, Reigate, showed Cymbidium Gattonense (A.M.), a hybrid between C. Traceyanum and C. Lowianium; it has bold handsome flowers.

FRUIT AND VEGETABLE COMMITTEE.

Mr. Gentle, gardener to Mrs. Denison, Little Gaddesdon, Berkhamsted, submitted a collection of forty dishes of beautiful potatoes, every tuber clean and fresh, and of good size. Up-to-Date, Ashleaf, Eldorado, Satisfaction, Sir J. Llewelyn, Royal Kidney, and Triumph were particularly good. Mr. Gentle also showed large bulbs of Ailsa Craig, Cocoanut, and Record onions, all clean and well finished. Some finely-preserved apples were exhibited by Messrs. J. Peed and Son, West Norwood, S.E., and the collection of about thirty dishes contained fine specimens of Lane's Prince Albert, Hambling's Seedling, Tyler's Kernel, Bismarck, Withington Fillbasket, Annie Elizabeth, Tebbutt's Pearmain, Lord Derby, Belle de Pontoise, and Hawthornden.

AWARDS.

Award of Merit.—To Nephrolepis exaltata Amerpohli, from Messrs. H. B. May and Sons, Upper Edmonton; to Blickling pear, from Mr. W. Allan, gardener to Colonel the Hon. C. Harbord, Gunton Park, Norwich; Cypripedium Mr. F. Sander, from F. Wellesley, Esq., Westfield, Woking; C. Fairieanum Cookson's var., from N. C. Cookson, Esq., Oakfield, Wylam-on-Tyne; Cymbidium Gattonense, from Mr. W. P. Bound, gardener to Sir J. Colman, Bart., Gatton Park, Reigate.

MEDALS.

Silver-Gilt Knightian. — Mr. Gentle, gardener to Mrs. Denison, Little Gaddesdon, Berkhamstead.

Silver-Gilt Banksian.—Messrs. H. B. May and Sons, Edmonton.

Silver Flora.—Messrs. H. Cannell and Sons, Swanley; Messrs. Sutton and Sons, Reading; Messrs. J. Waterer and Sons, Bagshot; Messrs. W. Cutbush and Son, Highgate; Messrs. Charlesworth and Co., Bradford; Messrs. J. Cypher and Sons, Cheltenham; Messrs. J. and A. McBean, Cooksbridge, Sussex; Mr. Balmforth, gardener to J. Mentieth Ogilvie, Esq., Oxford; and Messrs. Armstrong and Brown, Tunbridge Wells.

Silver Knightian. — Messrs. J. Peed and Son, West Norwood, S.E.

Silver Banksian.—Messrs. Hugh Low and Co., Bush Hill Park, Enfield (one for orchids, and one for carnations, etc.); Mr. H. Burnett, Guernsey; Mr. L. R. Russell, Richmond; Messrs. James Veitch and Sons, Chelsea; Messrs. J. W. Moore and Co., Rawdon, Leeds.

Croydon Gardeners' Society.

The annual dinner of this flourishing society was held on Wednesday evening last at the Greyhound Hotel, Croydon, when the president, J. J. Reid, Esq., filled the chair, and Mr. John Heal, V.M.H., was vice-chairman. Dr. T. Jackson, Dr. Voelcker, and Messrs. Oxtoby, Gregory, P. Bunyard, W. Humphreys, W. A. Cook, H. Boshier, W. Bentley, and R. B. Leach, were among those present.

The tables were charmingly decorated; indeed, the flowers are always a pleasing and very fine feature of this annual function.

Following the loyal toasts, Mr. John Heal proposed "The Society," and, in so doing, complimented the society on its achievements and its admirable management; he urged the wider use of such societies, and asked that the elder experienced men should welcome and assist the younger members. He appealed to the young men not to be copyists, but keen observers. Mr. Heal spoke of the good resulting from visits to horticultural establishments, and concluded with an appeal for a little help for the Gardeners' Orphan Fund. Mr. Oxtoby responded, and said he thought the old adage that "an ounce of practice was worth a pound of theory" was too rigidly adhered to by many men.

Mr. P. F. Bunyard proposed "Kindred Societies," and alluded to the fact that it was from the Croydon Society that the idea of drawing all horticultural mutual improvement societies into one federation emanated. They were always glad to welcome members from other societies to their lectures or their social functions. Dr. Voelcker, Analyst to the R.H.S., and Mr. Squire, of the Sydenham Gardeners' Guild, responded, the former expressing the opinion that the subject of the utilisation of atmospheric nitrogen for soil fertilisation had advanced but little during the past two or three years.

Mr. Mills proposed "The Horticultural and Local Press," and Dr. Jackson proposed "The Chairman."

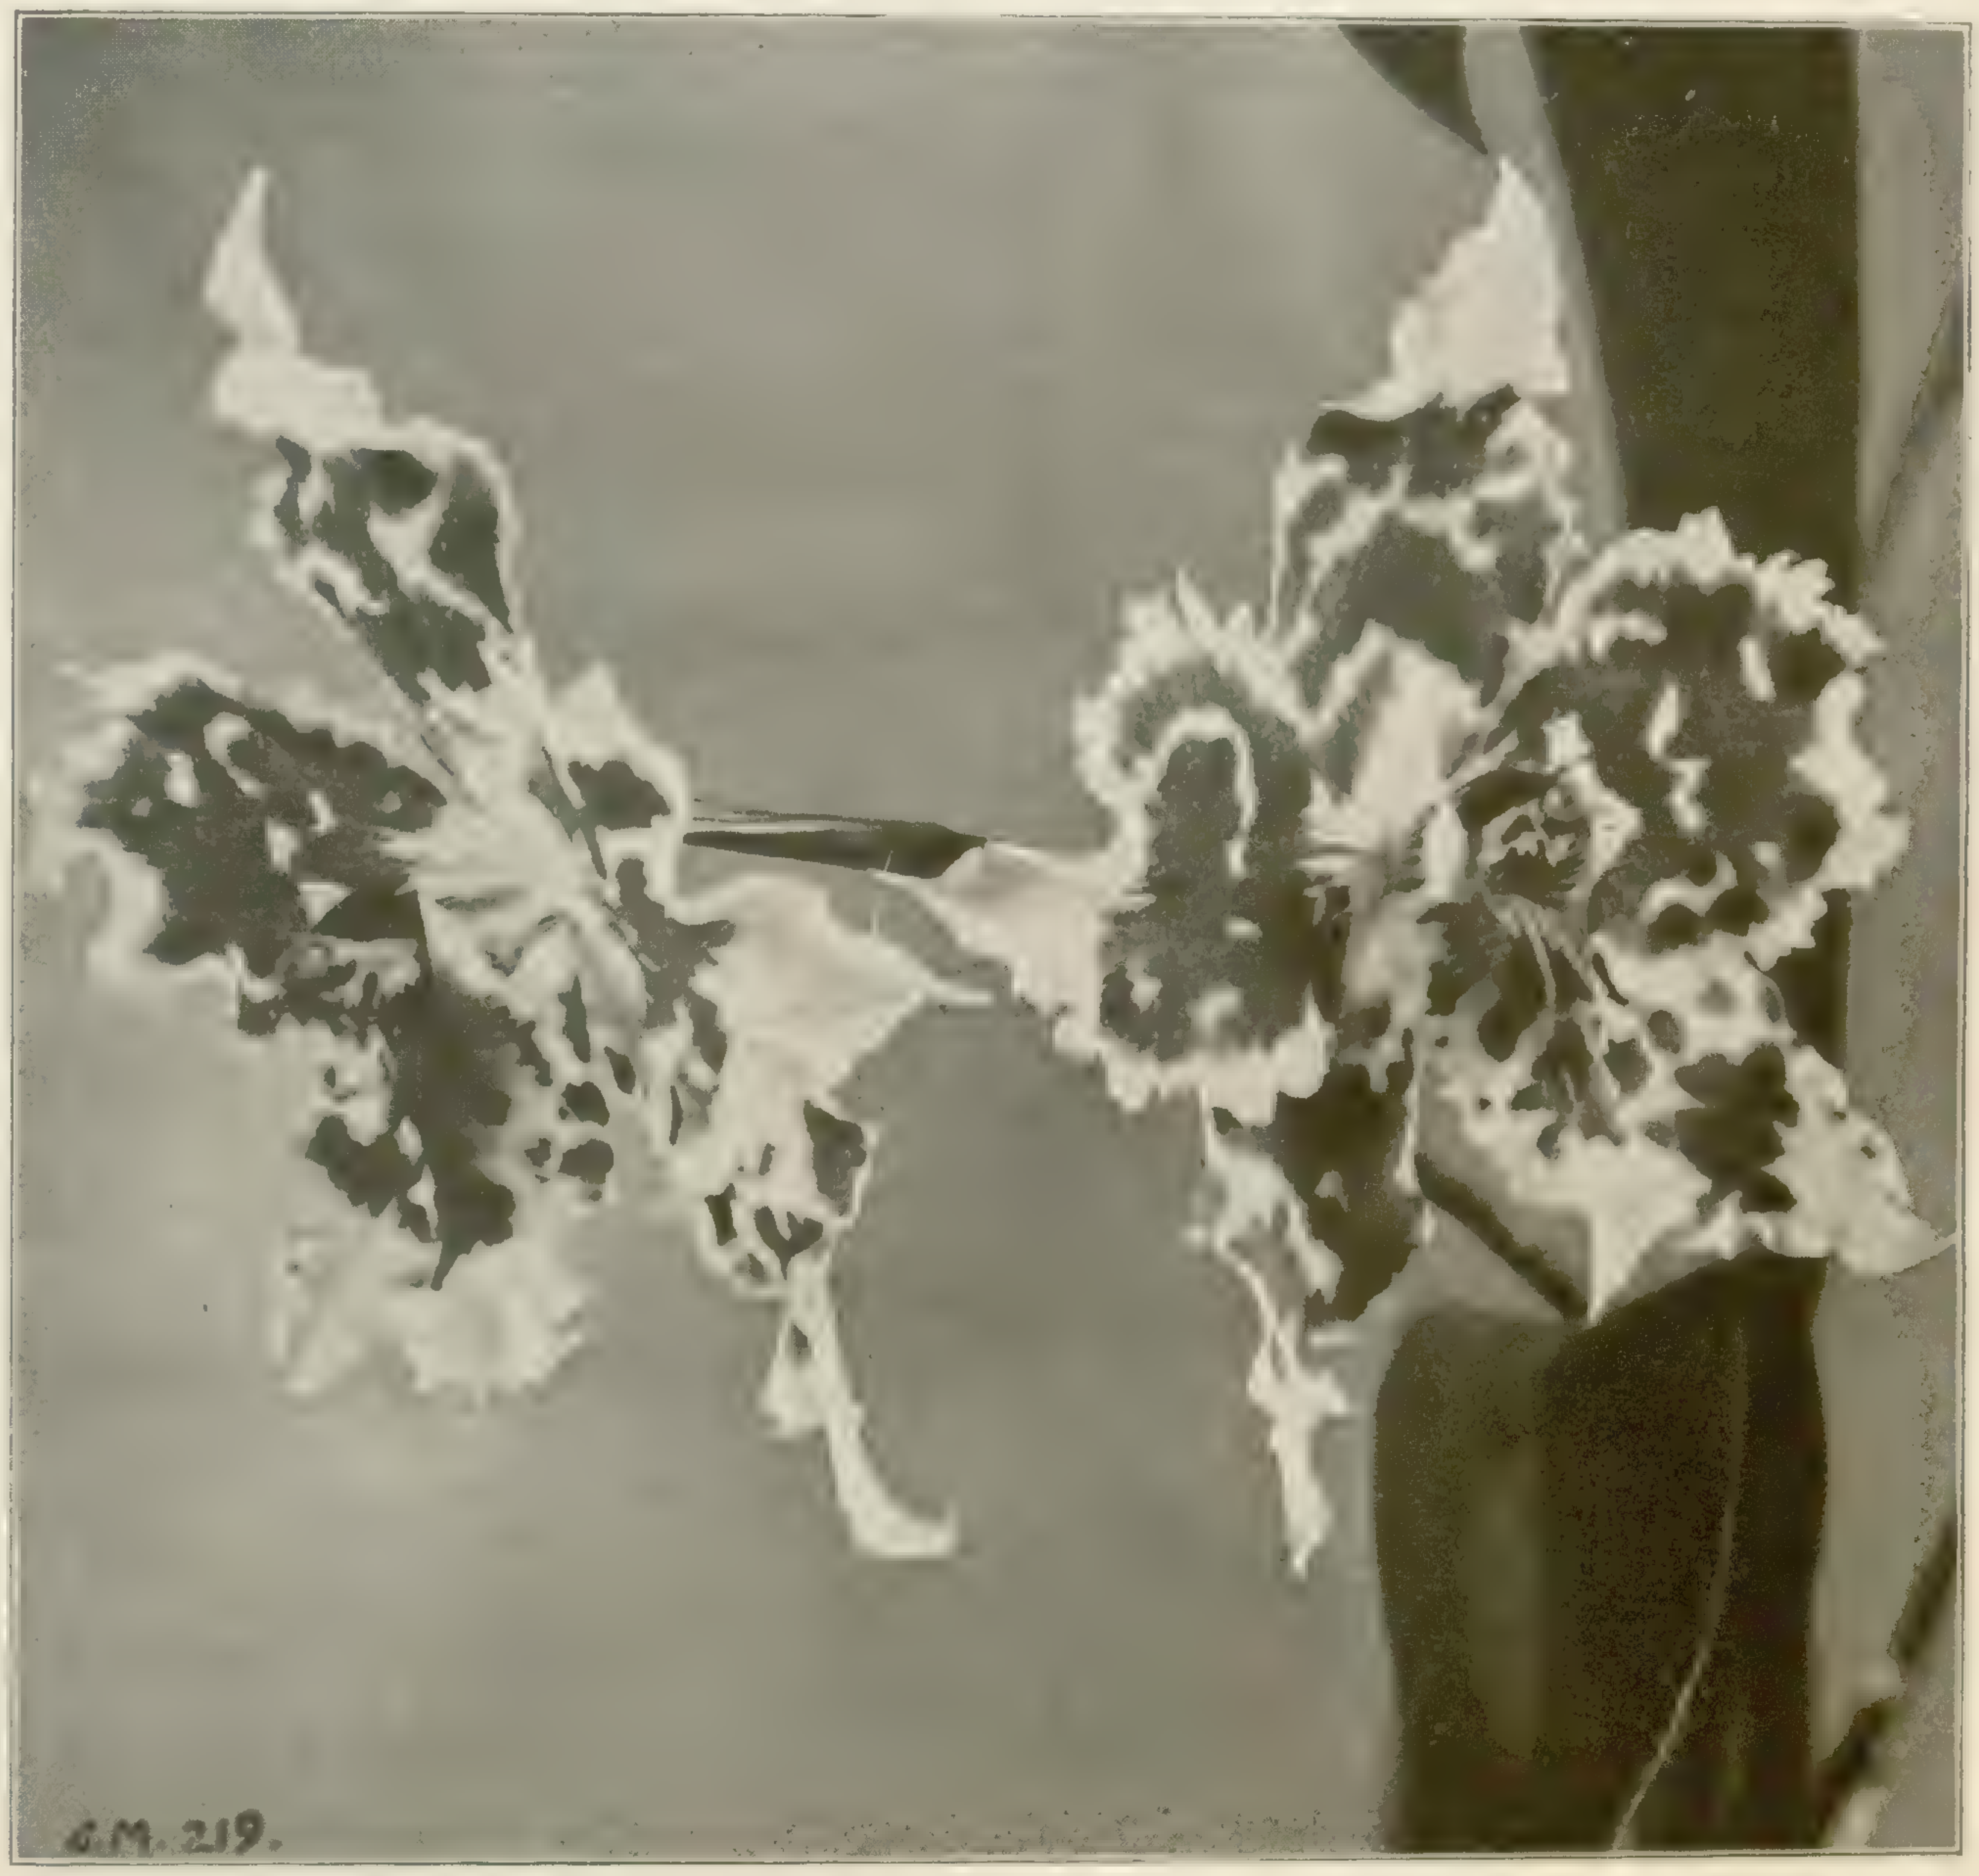
Royal Oxfordshire Horticultural Society.

The seventy-seventh annual meeting of members was held recently at the Municipal Buildings, Oxford. The Mayor (Alderman Ansell) presided, and there were about a score of subscribers present. The report, which had been printed and distributed, indicated the general good quality of the productions staged in competition, and regretted that, owing to the very showery weather on the occasion of the June and August shows, the result of the year's work was a loss of £90. The society has, however, a cash reserve of £114. James Herbert Morrell, Esq., Headington Hill Hall, was chosen president, and the society's fixtures are: Commemoration show, June 23; autumn show, August 27.

Liverpool Horticultural Association.

The annual meeting of this society was held on Saturday last at the offices in Victoria Street, Liverpool. The accounts submitted to the members proved the most unfavourable known for many years. The income from the spring show was £76 4s. 4d., the chief items being door and tickets, £43 19s. 10d.; and special prizes, £24 8s. 6d.; against expenditure £213 3s. 9d., including prize money £99 18s. 6d. From the autumn show were received by door and tickets £60 8s. 5d.; special prizes, £12 12s.; total income, £83 16s. 10d.; expenditure, £272 13s. 5d., including prize money, £150 1s. The general account showed a balance from last year of £162 15s.; subscriptions, £268 10s. 9d.; advertisements, £27 12s.; making, with other items, a total of £465 5s. 6d. On the other side were: Loss on spring show, £136 19s. 5d.; loss on autumn show, £188 15s. 6d.; other items, £88 11s. 1d.; making a total of £412 7s. 10d., leaving a balance of £52 17s. 8d., or a loss on the year's working of £109 17s. 4d.

The accounts were passed, and, after some discussion as to the future, the meeting was adjourned so that the statement of accounts might be sent to all subscribers with a circular pointing out the importance of united help if the society is to continue its two shows on the present basis. Surely Liverpool will answer the call of the committee, as it would be disastrous to the cause of horticulture if the magnificent spring exhibition held under the auspices of the association were to cease.



ODONTOGLOSSUM CRISPUM JEAN LINDEN.
Exhibited by Messrs. Linden and Co. at R.H.S. Meeting on Tuesday last. Flowers blush-white, with heavy red-brown markings.

Abingdon Horticultural Society.

This society, under the chairmanship of Mr. Councillor Brewer, held its annual meeting recently, but very few members were present. The report announced a satisfactory year's working, the "gate" at the August show being regarded as a record. Entries showed an improvement, each division of the schedule being well represented. The accounts gave a gain on the year of £17, and the reserve fund stands at £25 15s. 2d. The Right Hon. the Earl of Abingdon was elected president, and the date of the show was fixed for August 13.

Horsham Horticultural Society.

The past year has proved an exceptionally good one for this society; the summer and autumn shows held in connection therewith having proved a record in every way, resulting in a profit on the year's working of about £20. The balance now accredited to the society amounts to £47 5s. 3d. There was a slight falling off in subscriptions, but this was made good by extra attendance, induced by greater attractions at the shows. The dates fixed (provisional) for holding the shows during the present year are August 27 for summer show, and November 11 and 12 for the autumn one.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

COCKROACHES.—J. P., Bewdley: Yes, the specimens sent represent the pest that is all too well known under the name of cockroach. We are glad to have your experiences, and pleased to know you are achieving success.

PLATYCODON GRANDIFLORUM. — J. K., Essex: The plant named cannot be considered as inferior or superior to the Canterbury Bell, as it does not come into competition or comparison with it. Platycodon grandiflorum is a close relative of the campanulas, and was introduced in 1782. It is a native of China and Japan. The type rarely grows more than a foot high, but it produces many large and broad blue flowers. It is a species, and not a florist's production, and is usually cultivated in the front of a herbaceous border or on the rock garden. If seed is obtainable it will be probably through those firms who make hardy plants a speciality.

SWEET PEAS.—R. B. G., Redditch: The best advice we can give you is that you purchase "Sweet Peas and Their Cultivation" (1s. 2d. post free; W. H. and L. Collingridge, 148 and 149, Aldersgate Street, E.C.), and join the National Sweet Pea Society. The hon. secretary, Mr. C. H. Curtis, Adelaide Road, Brentford, will be pleased to forward particulars if you send him a postcard asking for them. In our own columns we pay considerable attention to the needs of sweet pea lovers, but, necessarily, there are many other subjects and interests to be considered.

ERECTION OF SUN-DIAL.—G. O., Harrow: If it is a horizontal dial, already marked and fixed, then when it is placed in position it must be made perfectly horizontal, and be correctly oriented. A spirit level will serve to show correct levelling, and the dial plate is turned until the shadow cast by the stile indicates the time shown by a correct watch. If your dial has the usual triangular stile, about a quarter of an inch thick, then the solar time indicated by the shadow will be one minute fast in the morning, and one minute slow during the afternoon. The hour lines of one dial will not suit all latitudes, hence a dial ruled for the London district would not be suitable for Glasgow. Perhaps your better plan will be to obtain the services of some competent firm, such as those who advertise sun-dials in our columns.

UNDERGROWTH. — W. B., Sydenham: The wood is too well drained by reason of its position, and the deep paths cut through it. But even if this is granted the charming wild flowers you name should grow under the trees if the leaf-soil is not removed. Oxalis, hardy cyclamens, pulmonarias, daffodils, snowdrops, ornithogalums, squills, etc., should do well near the paths if some little care is taken to plant them in good soil. Further, by extending the work over several years there is no doubt the undergrowth could be materially improved by planting groups of various berberis, mollis azaleas, rhododendrons, Leycesteria formosa, Symphoricarpus racemosus, etc., in the best positions and in good soil on prepared sites. these should all receive needful attention for a year or two until thoroughly established. Could not cuttings be made in the sides of the paths to carry surface water into the woodland among the trees and undergrowth, instead of carrying it all away? If this is possible there should be considerable improvement as a result, and the moisture-loving subjects could be grouped near these outlets.

SEEDLING LETTUCES FOR SALAD.—S. H. J., Wellington: Select a strong-growing cos variety, and sow the seeds rather thickly in shallow boxes of rich sandy soil. Cover the seeds very lightly with soil, water them in, and then stand the boxes in a cucumber pit or other structure where there is a temperature of from 60 to 75 degrees. Germination will soon take place. There is no need to place the boxes close to the glass, as one wants to secure tender leafage as quickly as possible, and a little "drawing up" will assist this object. When the seedlings are three or four inches high they may be cut over like mustard and cress. A few boxes of seedling lettuces to follow each other in this way may often tide one over an awkward gap between crops.

FORCING PARSLEY.—F. P. C., Warminster: Parsley is rarely forced in the usual sense of the word, but it often happens that the supply of parsley runs short early in the year. The shortage is due chiefly to the fact that all the foliage produced last autumn has been picked and the cold, dull weather has not encouraged new growth. If this is the case, then lift a few dozen roots carefully, remove old useless leaves, and trim the roots slightly; place these in pots or deep boxes, in sandy leaf-soil made firm, and then set the pots or boxes in a warm greenhouse. If much heat is given the end in view will be defeated; but a temperature of 55 deg., rising a little by sun-heat, will soon cause the plants to break into new growth. If any of the plants throw up flowering stems cut these back, as new leafage will be produced at the base in the plant's attempt to flower.

MOSCHOSMA RIPARIUM.—S. T. B., Walton: Cut back the plants as soon as they have ceased to flower, and begin to look shabby. Stand them on a warm greenhouse shelf, water sparingly, and in a few weeks as signs of growth are apparent, place them in a warmer, moister house. When the new growths are three inches long remove them, with a heel of old wood, by means of a sharp knife, and insert them in pots of sandy soil. If these cuttings are placed over gentle bottom heat in a close pit, they will root readily. They must be potted singly when well rooted, and as soon as they have taken hold of the new soil they must be removed from the pit to a light place in an intermediate house. During the summer they need little artificial heat. Pinch out the points of growth about twice during the earlier period of growth; if pinched oftener more spikes of bloom will result, but these will be small and ineffective.

TO PREVENT CLUBBING. — H. E., Wells: The fungus that produces "clubbing" in the roots of plants of the Brassica famil is one that retains its vitality for a lon time, and one, also, that can be conveyed fro plot to plot or garden to garden on one' boot soles, by horses' hoofs, by barrow cart wheels, on tools, and in many other ways. It is a horribly insidious pest. Heavily dre the land with fresh gas lime, breaking th down finely and spreading it over the s surface. Then proceed to dig or trench t plot, allowing the surface to remain roug for six weeks afterwards. After this peri has elapsed fork down the surface and s or plant any but a brassica or turnip cro. Lime is very useful for combating clubbing, and if the ground is in good condition otherwise, and does not contain an excess of lime, then use this material freely for a year or two.

MAKING A SMALL HOUSE PROFITABLE.—E. A. H., Hornsey: Whatever the crop grown the profits from so small a house would naturally not be large, though they might be good relative to the money invested and the labour expended. However, so much depends upon the care bestowed, knowledge possessed, and opportunities for the sale of the produce, that we cannot give you a decisive answer. You do not tell us the position of the house, or whether it is heated or not, so that we have little informatio to proceed upon. If one has a circle friends who possess small gardens, somethin may be done by raising good batches of seedlings of popular summer flowers and selling the plants at so much per dozen; many people would be glad to be relieved of the trouble and risks attendant upon seed sowing of annual and biennial subjects. Tomatoes could follow these, and bulbs, gently forced, follow the tomatoes, if the house in a light position, and provided with suitable artificial heat.

FLOWERING HEDGE. — J. C., Brentwood: The position receives so little sunshin that the success of a flowering hedge is somewhat doubtful. If the thorn is at all ta or dense then two-thirds of the hedge wi receive only the sunshine that filters throug it during the morning. Sunshine is necessary to ripen up the wood to induce freedo of flowering in a hard-wooded subject. lilac hedge would do fairly well, but it is useless if severely trimmed in; if the positio is sheltered from east winds Berberis Darwi might be tried, but it also would not prov effective if severely clipped, and the same remark applies to practically all flowerin hedges. Pyrus or Cydonia japonica shou succeed as well as most things, but it rather slow growing at first. If the soil heavy and moist your difficulties will be increased, but if moderately light and wel drained then fair success with the subjec indicated should be obtained.

NAMES OF PLANTS.

O. J., Cardiff.—Send again when in flower

C. R. C., Epworth.—1, Luculia gratissima 2, Aralia Chabrieri; 3, Plumbago rosea; Maxillaria stricta.

L. E. B., Maidenhead.—1, Euonymus radicans variegata; 2, Chimonanthus fragrans 3, Viburnum Tinus lucida.

B. M., Bradford.—1, The Kumquat variety of Citrus japonica; 2, Ardisia crenulata; 3, Oncidium pubes; 4, Begonia fuchsioides; 5, Galax aphylla.

A. D. T., Saltaire.—1, a fine form of Anthurium Schertzerianum; 2, Azolla pinnata 3, a very good form of Primula obconica, it gives no evidence of hybrid descent.

NAMES OF FRUIT.

F. E. B., Leicester.—Appears to be shrivelled specimen of Cellini.

H. T., Torrington.—1, Mère de Ménage; 2, not recognised; 3, Allington Pippin.

M. S., Newark.—1, Emperor Alexander Court Pendu Plat; 3, Beurre Rance; 4, Ca lac.

G. K., Brockhampton.—1, Lane's Prince Albert; 2, Claygate Pearmain; 3, Dumelow's Seedling.

GARDENING AND GARDENERS.

Time and again discussion arises in the horticultural Press upon the status or social standing of the gardener. What is the outcome of it all? It seems to me that all these discussions and agitations over raising the position of the gardener just fizzle out like the small boy's fireworks, and leave things pretty much as they were before. The reason is that the subject is not handled in a right spirit. There is always something of selfishness lurking in the arguments and suggestions put forward, and while this is so no good will come.

Almost invariably one of the first things brought forward by writers on this question is some sort of scheme whereby all those who are dubbed "labourers," "interlopers," or "outsiders" should be driven from the ranks so that the "Profession" may be reserved for qualified men only. This, surely, is selfishness, and more than that, it is foolishness.

For years there has been an outcry of "Back to the Land." The working man has been urged to refrain from crowding into the city or town, and to follow the healthier pursuits of land work. Now comes the suggestion that gardening should be reserved for the qualified gardener. Suppose this came about. What are those to do who are cast out? Further, who is going to select the qualified from the unqualified? To suggest examination as a fair means is just twaddle. What might suit the examiner might not suit the employer, and vice versa; and, after all, the employer is the one to judge of a man's capabilities. So long as a man discharges the duties that devolve upon him to the satisfaction of his employer, no power in Britain (who boasts her freedom) has a right to cast that man aside as incapable.

I have been from boyhood engaged in gardening, and have worked my way as best I could. As to the respect that has been shown me I have nothing to complain, for I do not think the fact that I am a gardener has made any difference to other people's opinion of me. That there is plenty of room for improvement in the financial position of the gardener I readily agree. The gardener is by no means the only one who could well do with a larger share of this world's goods. I believe, too, in elevating the profession to the highest possible position, but I am convinced this will never be accomplished by any barricading scheme.

Better far foster more of the "Help one another" spirit, and thus give each other a kindly lift. To all who would see the position of the gardener improved I would say, give greater support to the Gardeners' Mutual Improvement Societies, where such exist, and where they do not, set about organising them. Study more, impart the knowledge gained to others. Stand by the GARDENERS' MAGAZINE and other journals which are a power for good, and finally make the best of your own opportunities, and you'll find there is not so very much wrong after all.

A GARDENER.

When the Wallflowers Have Been Killed. — The winter has been a very trying one for wallflowers, many of the strongest of the old stagers in my garden having collapsed along with the youngsters. Fortunately, my beds also contain bulbs, so that I still look forward to a good display. But where a bed contains—or did contain—nothing but wallflowers and these have been so reduced in numbers as to be ineffective, I have found, from past experience, that there is nothing better to take the place of the dead than St. Brigid anemones. These can be planted at any time, and, though they would not bloom from a present planting so early as would wallflowers, they are so beautiful when in flower that nobody should mind waiting for them. My strain contains a good percentage of bright red doubles, and nothing makes a finer display in the garden at any season.—E. J. K.

THE GARDENERS' MAGAZINE.

NOTES OF THE WEEK.

The National Chrysanthemum Society.

The report and financial statement that were presented to the members of the National Chrysanthemum Society at the annual meeting, held on Monday last, indicate a state of affairs that fully justifies considerable apprehension with regard to the future. There was, it is true, an increase of £6, plus a few shillings, in the amount received as subscriptions, and this, as far as it goes, is satisfactory; but, unfortunately, this trifling improvement is outset by the statement that the comparatively large sum of £70 had been transferred to the general account to meet current expenditure. According to the balance-sheet this transfer leaves the society with a balance of £53 15s. 4d. with which to commence the current year's work. Notwithstanding the society's position, we look in vain in the report for any mention of such change of policy as would be likely to effect an improvement in the society's affairs. It is stated in the report that the committee "have, however, resolved to re-transfer not less than £25 to deposit account from the current year's income, and to continue the same policy until that account is restored to at least its original figure," which, at the commencement of last year, was £120. This resolution is an excellent one, but it is necessary to point out that a resolution, however good, cannot assist materially in the restoration of the society to prosperity unless practical effect can be given to it. The committee may have formulated a scheme, of which we know nothing, for accomplishing this, but if the £70 required for restoring the balance of income and expenditure, and the £25 for investment, are wholly obtained by a reduction of the prizes, there will be a falling off in the competitive classes sufficiently serious to injuriously affect the reputation the society has enjoyed for the excellence of its exhibition. Some reduction in the prize list will, of course, be necessary, but there will have to be reductions in other directions apart from the abolition of the judges' fees. We are inclined to the opinion that a complete reorganisation of the executive would be advantageous, but as so drastic a measure as this is not likely to be taken, we suggest that an endeavour be made to reduce the cost of administration, which appears to us out of proportion to the annual income. Some of our readers who take an interest in chrysanthemums are greatly perplexed by the present position of the society, but to us there appears no difficulty whatever in correctly assigning the cause of the decline in its popularity and financial resources. The National Chrysanthemum Society is now suffering from the failure of the executive to recognise the fact that a society which claims to be national in its aims, as well as in name, should do something more than hold exhibitions, and should differentiate its functions very clearly from those of a local organisation. When by strenuous efforts the society had some twenty years ago been placed in a strong position, financially and otherwise, a few members of committee with advanced views formulated a scheme for the preparation of a catalogue which would serve as a work of reference on matters of classification, which was then in an unsatisfactory state. This scheme was accepted by the committee, the catalogue was prepared, and published, and proved a huge success Members, as well as the outside public, were charged for the catalogue, and a big profit resulted from the sales. Two or three editions were subsequently issued, but when the publication ceased to be a source of profit the issue of literature was abandoned until within quite recent years. In this connection two mistakes were made; one was charging the members for the catalogue instead of presenting it to them as part of the advantages they received in return for their subscriptions, and the second was the disbursement of the profits on literature in prizes. At that time the members of the society were distributed in large numbers over the whole of the kingdom, and as many of them were unable to either compete for prizes or visit the shows, they, in course of time, became tired of subscribing annually merely for "the good of the cause." It is all the more surprising the majority of the committee should in those days have failed to appreciate the necessity for giving members something more than the ticket of admission, seeing that the literature had the effect of placing the society at the head of all the other organisations associated with the chrysanthemums, and of enormously increasing the number of societies in affiliation. The society is now suffering not only from a failure to adopt a policy that would appeal to a wide circle of those interested in chrysanthemums, but also from a want of prudence in not having formed a substantial reserve fund when at the zenith of its prosperity, as was so strongly urged at the time by a few who were able to see beyond

MR. WILLIAM F. E. S. STEPHENS,
Treasurer of the Dahlia Union.

the range of vision of those forming the majority of the committee. At that time the formation of a reserve fund of £500 or more would have been a comparatively easy matter, and with some such sum as this available, there would, we should imagine, be no great difficulty in initiating and carrying out a policy that would greatly improve the fortunes of the society. As matters now are the difficulties in the way are such as to require the greatest care on the part of the committee, and the liberal support of those who are specially interested in chrysanthemums.

Mr. William F. E. S. Stephens, of St. Andrews, Spring Grove, Isleworth, is an amateur who is already well known among dahlia growers, but who, if given health and strength, is likely to be more widely known in the near future among lovers of roses and sweet peas. For about twenty years Mr. Stephens has been a successful exhibitor of flowers and fruits, but cactus dahlias are his favourites, and with these he has won many prizes at the old Royal Aquarium, at the Crystal Palace, and Regent's Park, as well as at local shows. He has been a member of the National Dahlia Society's Committee for many years, and has acted on the governing body of the London Dahlia Union since its inception; he is now the treasurer of that body, and at its exhibition in 1907 he won the Hobbies' Challenge Cup in excellent style. Mr. Stephens is a Fellow of the Royal Horticultural Society, a member of the National Sweet Pea Society, and a member of the National Rose Society. In this latter connection we may observe that Mr. Stephens has recently planted two hundred H.P. and H.T. roses with a view to exhibiting. Mr. Stephens is an ardent amateur horticulturist, and cultivates his large garden with great skill, finding in it a splendid source of health and recreation after his trying work as clerk to the Brentford District Board of Guardians.

R.H.S. Meeting on Tuesday next will have a special attraction for those who take an interest in potatoes, whether as cultivators or raisers. Messrs. Sutton and Sons will exhibit a collection of potatoes remarkable alike for its magnitude, its representative character, and its high quality. The exhibit will include, not only all the best varieties in cultivation, but the finest collection of the wild types yet brought together.

American Carnation Society.—The annual exhibition and conference of this society was held at Washington on January 28, and proved highly satisfactory, the display produced being extensive and of high quality, while the conference was of much interest. Mr. F. H. Lemon, of Richmond, Indiana, the president of the society, gave an excellent address at the opening of the conference, and touched upon several matters of interest to growers of carnations in this country. With reference to the discussion that has taken place with regard to the value of the society's certificates, he endorsed the opinion of Mr. W. N. Rudd, that "the certificate is nothing except an opinion of the quality of the flower shown at the exhibition. The commercial value of the carnations must be shown in other ways." He further pointed out that it is beyond the province of the society to attempt to say whether or not a certain carnation shall prove a profitable investment to the buyer. With a view to a recognition of varieties that prove of value to growers, Mr. Lemon suggested that the raiser of any variety which wins the first prize in an open class for three consecutive years should be granted the society's gold medal, suitably engraved. Mr. Lemon also urged the importance of the American Carnation Society's providing classes for collections in pots and decorative displays, and in his remarks pointed out that both would materially enhance the utility and interest of the exhibitions. With regard to the success which is being achieved in this country in the raising of new varieties, Mr. Lemon said that, taking into consideration this fact, it would be an advantage to make some arrangement whereby new English varieties could be sent to America for testing their adaptability to the climate and market conditions that obtain in the United States. He thought probably an exchange of novelties could be made between growers in America and in England. The address necessarily contained much that was of immediate importance to American growers, but the points to which reference is here made are of equal interest to growers on both sides of the Atlantic, and we commend them to the consideration of our readers.

Royal Gardeners' Orphan Fund.—The annual meeting of this charity will be held at "Simpson's," 100, Strand, W.C., on Friday, the 14th inst., when thirteen children will be elected to the benefits of the fund. The chair will be taken by Mr. H. B. May, chairman of committee, at 3 p.m., and the poll will close at 4.30 p.m. There are seventeen candidates. The friendly dinner of the committee and friends will take place at "Simpson's" on the evening of the same day.

Royal Horticultural Society.—The following list of president, vice-presidents, members of council, and officers for election on Tuesday next has been circulated among the Fellows, in accordance with Bye-law 74: President, Sir Trevor Lawrence, Bart., K.C.V.O., V.M.H.; treasurer, Mr. J. Gurney Fowler; secretary, the Rev. W. Wilks, M.A.; members of council, the Hon. John Boscawen, Mr. E. A. Bowles, M.A., F.L.S., Mr. J. Gurney Fowler, and Mr. W. Marshall; vice-presidents, the Right Hon. Joseph Chamberlain, the Right Hon. the Earl of Ducie, the Right Hon. Lord Rothschild, Baron Sir Henry Schröder, Bart., V.M.H., Sir John T. Dillwyn-Llewelyn, Bart., V.M.H., and Leopold de Rothschild, Esq.; auditor, Mr. Alfred C. Harper. As the number of names proposed does not exceed the vacancies to be filled, there is no need for a ballot.

Gardeners' Royal Benevolent Institution.—Lord Aldenham has accepted the invitation to preside at the anniversary festival dinner in aid of the funds of this institution at the Whitehall Rooms, Hotel Metropole, June 24.

Black Scab Disease of Potatoes.—From the South-Eastern Agricultural College, Wye, we have received a copy of Mr. E. S. Salmon's brochure on the black scab, or warty disease of potatoes, caused by the fungus known as Chrysophlyctis endobiotica. The disease is fully described and illustrated, and an account of its present distribution is given. Mr. Salmon urges potato growers and merchants, farmers, market and private gardeners, and allotment holders, to take immediate steps, by means of resolutions or deputations, to awaken the Board of Agriculture to the necessity for taking steps to repress this new potato disease before it is too late.

Forestry at Cambridge.—A chair of forestry has been established at Cambridge, and Dr. A. Henry, who has contributed so materially to our knowledge of the flora of Yunnan, has been appointed Professor of Forestry to the University.

The Gardeners' Company.—The Court of this company has decided to confer the honorary Freedom upon the Duke of Teck, president of the Royal Botanic Society; the Earl of Meath, chairman and founder of the Metropolitan Public Gardens Association; Lord Monkswell, chairman of the Kyrle Society; Professor W. A. Herdman, F.R.S., president of the Linnean Society; and Mr. F. S. W. Cornwallis, trustee and ex-president of the Royal Agricultural Society. A formal resolution in connection with the presentation will be submitted at a Court meeting at the Ritz Hotel on Tuesday, March 24, and the presentations will take place on May 19, at a ladies' dinner to be given by the Master, Sir Thomas Dewar—probably at Fishmongers' Hall.

Blickling Pear.—This good late dessert pear was exhibited by Mr. W. Allan, the veteran gardener at Gunton Park, Norwich, at the recent meeting of the Royal Horticultural Society, and on the official list of awards it was recorded as having received an Award of Merit. This was evidently an error, as the variety gained such award early in 1907, and was figured on p. 40 of the GARDENERS' MAGAZINE of that year.

Midland Counties Sweet Pea Society.—From the schedule of this newly-formed society we learn that the Right Hon. the Earl of Plymouth is president of the society, while among the vice-presidents and members of the Floral Committee we find many noted enthusiasts, including several connected with the National Sweet Pea Society. The society's first show is to be held in Wolverhampton on July 29, 1908, and the prizes offered amount to £70. In addition to this, several medals will be awarded. The hall where the show is to be held is a fine one. The hon. secretary is Mr. Owen F. Trott, 104, Waterloo Road, Wolverhampton.

R.H.S. Trials at Wisley.—The trials at the Royal Horticultural Society's Wisley gardens during 1908-9 will include herbaceous phloxes, cannas for bedding, early-flowering chrysanthemums, cactus dahlias, asparagus, beet, Brussels sprouts, cabbage, parsley, and potatoes.

Interesting Botanical Study.—At the recent conference of teachers who work under the London County Council the subject of Nature Study occupied a large portion of the programme, and that portion of the subject dealing with botany was freely discussed. The chief points urged for making botany a more interesting and educational study were that pupils should study living plants, making notes and sketches of these at intervals over a lengthened period, and that they should themselves make experiments with living plants. It was further urged that teachers should prepare the lessons with great care, but at the same time leave as much as possible for the pupil to do; and that teachers should not forget the beauty and value of living plants while studying them or using them for teaching.

A Berlin Rose Garden.—According to a correspondent of "La Tribune Horticole," a new rose garden has been formed in the vicinity of Berlin, which is described as the largest garden of its kind in the world. The garden will, it is stated, be not only attractive during the season of roses, but will serve as a place of instruction in the art of rose culture.

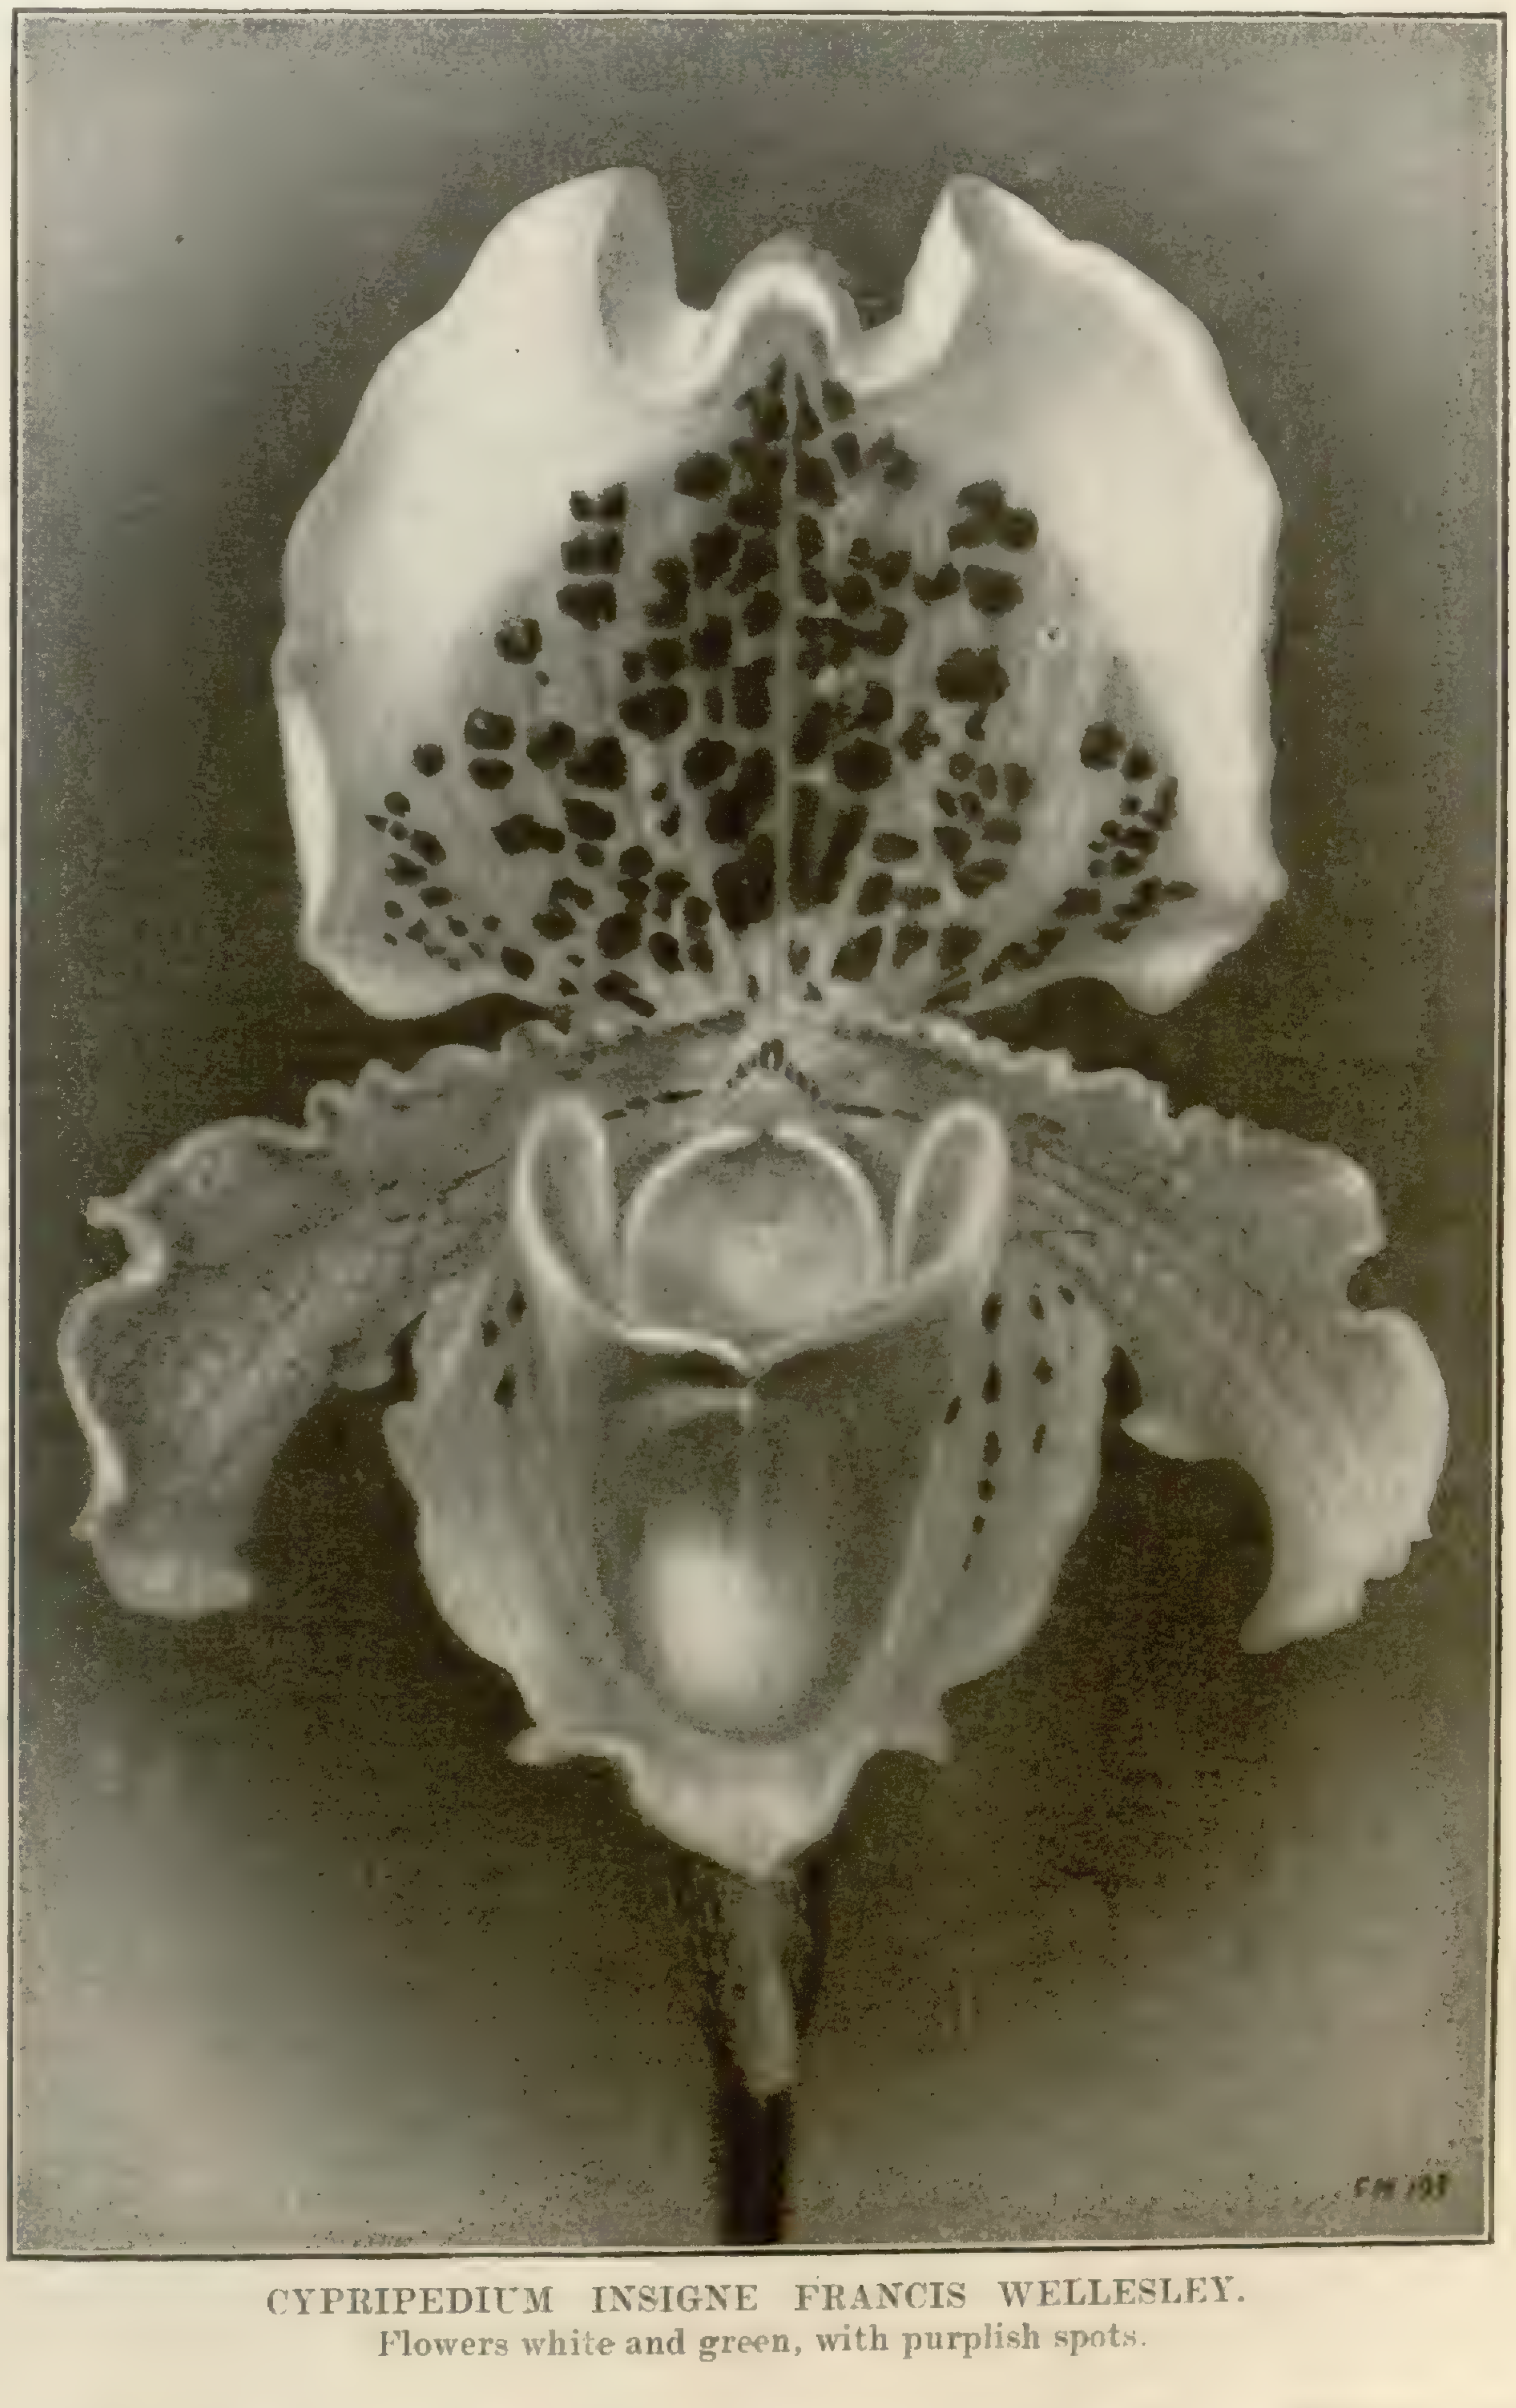
Croydon Gardeners' Association.—The programme for the first half of the current year includes the following papers: February 4, "Mushrooms," by Mr. Benger; February 18, "Insects," by Mr. H. Withers; March 8, "Flowering Shrubs," by Mr. A. E. Thatcher; March 17, "Grapes," by Mr. W. Lintott; April 7, "Peaches and Nectarines," by Mr. Seabrook, and April 21, "Ventilation," by Mr. Harris. The exhibition of spring flowers will be held on Wednesday, May 6. Mr. J. Gregory holds a class on Friday evenings at 60, Canterbury Road, Croydon, for preparing objects and materials for the microscope.

Origin of the Cultivated Potato.—The paper on the origin of the cultivated potato, presented to the Linnean Society by Mr. A. W. Sutton, V.M.H., is of special interest for the prominence it gives to the fact that so far it has proved impossible to identify the wild species to which we owe the innumerable varieties in commerce, since the earliest evidences of its introduction into Europe, and particularly a beautifully executed coloured illustration dated 1585, and authenticated by Charles de l'Escluse, indicate that it was the already cultivated plant which was introduced, and not the wild and presumably Chilian type. Mr. Sutton for many years has collected and grown all the known wild tuber bearing species, with a view to identification, but none agree at all closely in their specific characters with Solanum tuberosum, the name given to the potato by Linnæus. The nearest is a species, anomalously named, as well be seen, S. etuberosum, or the non-tuber-bearing potato, and it is this plant which has recently given evidence strongly pointing to its being the parental form of the cultivated varieties, in spite of certain specific differences in the foliage and habit, since not only does it produce edible tubers indistinguishable in size and flavour from medium-sized commercial potatoes, but after twenty years' sterility it produced in 1906 a seed berry, whence a batch of seedlings have resulted, which practically cannot be distinguished from a batch of ordinary potato seedlings. This fact is the more remarkable as the seeds of wild types yield, as a rule, true offspring generation after generation, while those of cultivated varieties produce mixed and variable progeny, and can only be propagated truly through their tubers. S. etuberosum was received by Mr. Sutton from the Edinburgh Botanic Gardens, as a wild specie whose habitat has not been recorded, but is undoubtedly Chilian. S. etuberosum has been growing at Reading year after year for twenty years, every year in close proximity to and under the same conditions as numerous varieties of ordinary potatoes, all of which have been subject to and suffered from disease season after season. In spite of this there has never been noted a trace of disease either in the foliage or in the tubers, S. etuberosum having withstood infection and remained immune during the whole time.

Site Selection for Fruit and Potato Crops.—It is generally understood by gardeners that a low-lying site is by no means an ideal one for fruit and potato crops, because of its liability to rapid falls of temperature at critical periods of the crop's life. That this understanding is well founded has been proved by experiments recently made near the river Stour, by Messrs. Vinson and Russell, of the Wye Agricultural College. Those experiments showed that the higher ground was much less liable to frost than the low ground not far from the river. The results are published at length in the "Journal of Agricultural Science."

GIANT CYPRIPEDIUMS.

There are several cypripediums that may reasonably be grouped as the giants of their race. Some have tall growth, and are giants when compared with the growth of others, and in this respect one may contrast C. longifolium with C. niveum. But it is to those that have very large, bold flowers that one wishes to draw attention, and here visions of C. Rothschildeanum, C. Gowerianum magnificum, C. Mrs. F. Wellesley, C. Beekmani, at once rise in the mind's eye. Two that also stand out conspicuously for their size, substance, and good form head and shoulders above their brethren, are C. insigne Harefield Hall variety, with its massive blooms and striking combination of white, green, and purple, and the newer C. insigne Francis Wellesley. The latter variety, now figured, even surpasses the splendid Harefield Hall variety, which it closely resembles in many respects. The illustration gives a very fair idea of this grand cypripedium, and shows particularly well the great breadth of the dorsal sepal and the manner in which this organ is broadened at the base. This latter feature is one in which it differs from the Harefield Hall variety. The broad green petals, wide ventral sepal, and capacious labellum are other features of interest, while the pure white band around the green, purple-spotted area on the dorsal sepal make the colouring most effective and distinctive. This fine new cypripedium is the property of Mr. Francis Wellesley, of Westfield, Woking, whose collection contains so many rare and beautiful plants.



CYPRIPEDIUM INSIGNE FRANCIS WELLESLEY.
Flowers white and green, with purplish spots.

Japan Wax.—It appears that the fatty material known commercially as Japan wax is obtained from the fruits of Rhus succedanea. Before germination the seeds contain fat but no starch, the latter being formed during germination.

PREPARING VEGETABLES FOR FORCING.

Where the necessary conveniences are available, no great deal of skill is required to force vegetables provided they are properly prepared for the purpose. It is on the culture of such vegetables as asparagus, seakale, etc., the plants for forcing, that success chiefly depends, though it does not appear at all times to be sufficiently considered, indeed, it is not at all an uncommon thing for plants considerably past their best bearing condition to be lifted for forcing. It is useless to expect material of this character, that in reality is unfit to yield good crops where grown in beds outdoors, to furnish those of high quality after being lifted and forced, but if young, vigorous plants are prepared, there will be no question about the quality of the produce. Then forcing will be of secondary importance.

Asparagus.

Of all vegetables commonly forced, the asparagus is perhaps the most highly esteemed, unfortunately it is rather particular about soil, being especially impatient of a stiff cold one, while it succeeds best in well-drained, deep, light loam—no other can be better than an alluvial one of this description—and in soils of this kind suitable plants for forcing can be readily prepared. Plants are raised from seed, which should be sown early in April, upon land that has been heavily dressed with good short manure, and deeply trenched in the previous autumn or early winter. When preparing the soil for the seeds it should be finely broken for a few inches in depth, and have its surface levelled, and the drills drawn fifteen inches apart and two inches in depth, to receive the seeds which should be thinly distributed, and carefully covered.

Summer treatment simply consists in keeping the ground clear of weeds, and lightly stirring the soil between the rows of plants with a Dutch hoe. In autumn as soon as the plants have matured their growth, they should be carefully cut down to the ground level, and as a winter protection be lightly top-dressed with decayed horse droppings, or coarse leaf-soil.

Transplanting should be done when the plants are either one year or two years old, the earlier time is however the best, because planting can then be done with less injury to the roots, and consequently less check to the plants, than in the other case. The most suitable season for the work is when growth commences, which is usually early in April. Transplanting should take place in an open situation, upon land treated in like manner to that recommended for seed sowing, the plants being placed two feet apart. When planting stretch a line across the plot and cut with a spade on either side of it, in such a way as to leave a low ridge beneath the line; upon this ridge the plants should be placed with their roots divided and spread out on either side. The soil should be firmly filled in, and levelled, and when the work, which should be done when the soil is dry, is completed, the crowns of the plants should be two inches beneath the surface of the soil. Subsequent treatment entails weeding, watering when necessary, assisting the plants with liquid manures, or top-dressing during showery weather with Peruvian guano, and cutting the plants down, and lightly mulching them in autumn with rich short manure. With careful attention upon these lines vigorous plants in excellent condition for forcing can be grown in four years.

Seakale.

Seakale can be readily raised either from seeds or roots. In adopting the latter means strong, healthy pieces of root about four inches in length, selected from plants while being lifted for forcing, and having their ends cleanly cut, should be arranged in a heap, and covered with fine ashes or light soil. Early in April these cuttings will have started rooting, and they should then be planted if intended for lifting for forcing, fifteen inches asunder in rows two feet apart, with the crown just beneath the soil. If the plants are to be forced on the ground where grown they should be placed at least two feet apart each way. At an early stage of growth the shoots must be reduced to one or two upon each plant, the strongest being reserved. The crop should have necessary supplies of water during summer, and after they are well rooted, soakings of liquid manure will assist in promoting vigorous growth and large crowns.

When raising plants from seed—by which means large quantities can be easily secured sowings should be made early in April, in drills placed about fifteen inches apart. Sow thinly, and thin the young plants early to six inches apart. Early in the following spring lift the plants, replant, and subsequently treat them in a similar manner to that recommended for plants raised from root cuttings, but before growth commences in spring cut the crown of each plant off, to prevent them running to seed; new growths will be quickly made.

Rhubarb.

Very commonly old plants of rhubarb are lifted for forcing, though far better results can be obtained by growing young plants for the purpose. The best course to follow is to divide strong plants at the time they are about to start into growth, securing a few good crowns to each and planting them three feet apart. With liberal treatment these will be fit for forcing the following winter.

For seakale and rhubarb land should be prepared thoroughly, because unless robust young plants are provided the forced produce cannot be of the best quality.

T. Coomber.

The Hendre Gardens.

Planting "Spiky" Flowers.—The great prevalence of bushy, flat-topped flowering plants in gardens during the summer must be noticeable to all observers, and it is, of course, due to the tremendous numbers in which the great composite family is represented in our gardens. To relieve this flatness, I hold that it is the duty of all real garden lovers to plant what I call spiky flowers, viz., verbascums, delphininums, foxgloves, larkspurs, antirrhinums, gladioli, lilies, montbretias, hollyhocks, etc. By making a note of this now and planting such things as they can be obtained from the nursery, the appearance of the garden can be greatly improved in the summer before us.—E. J. K.

Chrysanthemum, Mrs. J. Hygate.—If Mr. Barnes wishes to adhere to principle in maintaining each section of the chrysanthemum, he will place Mrs. J. Hygate amongst the Japanese varieties, where the introducer has placed it; grow it as well as he can, and he will find he will not regret putting it in the front row of a board, even if F. S. Vallis at the back is 16 inches in diameter. If he obtains the latter at the size quoted, and will give me an invitation to call and see it, I will with pleasure accept, no matter where; or, if he knows of any other grower with such blooms, I will go and see them, as I should consider I was spending my time very well indeed in doing so.—E. Molyneux.

BEAUTIFUL DWARF IRISES.

◆

I. Bakeriana.

This lovely little netted iris, although recognised as a distinct species, having a cylindrical eight-ribbed leaf, comes well under these notes. It is, however beautiful, not a reliable garden plant for the open, and many who were induced to purchase it through seeing a coloured-plate of the species, have had to bewail its loss. I. Bakeriana, which blooms very early indeed—January to March—suffers in our climate, and usually dwindles away in a year or two if in the open. It is simply exquisite, with its fragrant flowers of a beautiful blue, cream-colour or yellow, dotted with violet, and its yellow markings. It is very dwarf, and one of the irises which are perfect gems in the rock garden. It is a choice subject for pots.

I. Danfordiæ.

There is some difference of opinion as to whether this and I. Bornmuelleri are synonymous or not. All the bulbs I have had under either name were much the same, and all had the fault of I. Bakeriana that of not standing our winters well. It blooms from January to February, and gives small yellow flowers dotted with brown.

I. Vartani.

Of still less value is I. Vartani, a late autumn and winter-flowering species from the neighbourhood of Nazareth, with leaves which may be called four-sided, and rather dull-coloured lavender blooms, marked with yellow or white. It seldom blooms when in the open until well into winter, and is not a long liver in the garden, as it does not stand frost well. It is more suitable for the alpine house or the frame than the open.

Cultivation.

The greater number of these, and also the reticulata irises previously referred to, like any good garden soil, but ought not to be in too dry a place. The most vigorous plants of any of these irises I have cultivated were on the margin of a water lily tank, well above the water, but where the moisture was partly soaked up by the soil, but not to any extent. Here, the irises were more vigorous than in a drier place and this accounts for the preference apparently shown by them for peat, which holds the water longer than some soils. I prefer planting now about three inches deep as early as the bulbs can be purchased. They require little further attention except where the troublesome fungoid disease, to which this iris is subject shows itself. This is revealed by the premature withering of the leaves, and on the bulbs being lifted some of them will have been entirely destroyed, all but a husk covering a black powder or dust. Some of the bulbs will have black patches on the outside, and it is, in my opinion, safer to burn these, although some practice a simple removal of the coats and replanting the bulbs in a separate part of the garden. There is, however, great danger that this disease may be spread from such infested bulbs, and destruction is the only safe method. It may be added that in such weather as we generally have early in spring a handlight over the flowers will preserve them considerably longer in beauty than when left unprotected by glass. They are all charming when grown in pots. Such beautiful irises as these deserve all the care they require, and afford a vast amount of enjoyment to those who see them in the early months of the year.

Dumfries. S. Arnott.

FORESTRY AND THE PRESS.

The rapid development of modern enterprise and industry is already linking up various phases of life and work which hitherto had been practically strangers to each other. To the ordinary mind the connection between "Forestry" and "The Press" must at the first glance appear to be somewhat "far fetched." But really it is not so, for the marvellous developments of the Press, especially in the case of the daily papers and the cheap periodicals, has resulted in an enormous demand for paper, so that for some considerable time the forests of Europe have been laid under demand to provide the material necessary for the making of this class of paper.

Thus you see the connection between "Forestry" and "The Press." Now the point is this, only certain trees are suitable for making wood pulp, "the greatest component in the manufacture of paper, and chief among these is the white spruce. Abies, or (Picea) excelsa, one of the most widely dispersed trees of Northern Europe. Expert opinion has recently given us the news that the forests of Norway and the adjacent countries are being rapidly denuded of this Norway spruce, so quickly in fact as to point to a famine in this particular wood in the near future. Already one of the great publishing companies have formed a syndicate to take over the spruce forests of Newfoundland in order to insure themselves against this threatened famine in wood pulp.

Now, in view of the various schemes for reafforestation which are set forth from time to time in this country, surely a place ought to be given to the spruce fir, especially as properly planted stretches of land would provide a good investment for the future. It is estimated that thirty years are required for the young forests to arrive at maturity, and at the end of that time they will be in good condition for converting into the daily paper. To the forester and those who have the management of woodlands and estates, these notes will necessarily appeal, and where the position and soil will allow, the spruce should be readily planted. It will be understood that although good, clean, quickly grown timber is always at a premium, yet for the making of wood pulp, timber of a second-class description will be quite suitable. This, however, should not deter anyone putting their best work into this forest-planting, but should rather lead to the planting of sites which cannot be regarded as quite first-class.

The soil for the Norway spruce should be cool and moist, not necessarily deep, but the moisture must be there. They will grow well at fairly high altitudes, provided the position is not too much storm swept and exposed.

Undoubtedly on many of the larger estates, and the Crown lands, there is much waste ground, largely heathland, where the soil though fairly cool, is generally poor, and deficient in organic matter. It has been proved, however, that on such soils, with a proper system of manuring, spruce as well as other trees can be grown profitably and well. In manuring nothing answers so well as basic slag, which can be used up to the quantity of 15cwt. per acre. A much smaller quantity of kainit can be used with the basic slag, say about 2cwt. per acre, this combination giving splendid results. Manuring should be carried out before planting.

The mode of reafforestation of waste heath-land in Belgium calls for a brief notice. The heather is cleared in strips where the rows of trees are intended to be planted, then a good dressing of basic slag is given on the cleared strips, and is incorporated thoroughly with the soil by the operations of digging the trenches and planting the trees. In other cases, after the ground has been cleared and given a dressing of basic slag, a crop of lupins is sown, and is grown, and then ploughed in as green manure, thus providing a food basis for the trees which are afterwards planted. Sometimes following the green manuring of the lupins a crop of rye or oats is taken, and the ground is thereby in good cultivation by the time the forester is ready with his trees.

The questions of timber, and of reafforestation will come to the forefront very shortly, and all thoughtful lovers of the country, especially those who are interested in forestry, will assuredly give their full support to any thorough scheme for the advancement of the cultivation of timber trees in this country.

In its woodlands Britain has a smaller percentage, according to her area, than any country in Europe except Portugal, and it is estimated that we have about fifteen million acres of heath and mountain land to select from for planting. With the wide range of subjects for the various positions, soils, etc., there is surely no reason why this England of ours should not be a better-wooded and much larger timber producing land than it is at present.

P. S. Hayward

ROSE MRS. DAVID McKEE.

This charming hybrid tea rose is classed in the catalogue of the National Rose Society as "an exhibitor's rose." We have no doubt as to the correctness of this description, but we contend the variety has also much merit for garden decoration. It is a creamy-yellow rose, of a shade none too prevalent among roses, and it was introduced by Messrs. Alex. Dickson and Sons, of Newtownards, in 1904. It is a moderately vigorous grower, producing large, full blooms, made up of broad, smooth petals, and it belongs to what may be called the Kaiserin Augusta Victoria type. At Woburn Place, Addlestone, the residence of E. Mocatta, Esq., this new rose does well, and Mr. T. Stevenson, the gardener, who is an excellent cultivator, is also something of an artist, as the accompanying illustration from his photograph shows.

Creamy-yellow flowers.

HIPPEASTRUMS.

The cultivation of hippeastrums, commonly called amaryllis, has attained to such large proportions that in many gardens the plants are represented by hundreds.

To those conversant with these subjects the reason of their increased popularity is self-evident, their culture from first to last is simplicity itself; they are robust in habit, bold and stately in form, and for the most part refined in their colouring, which, in a large percentage, partakes of a bright scarlet or crimson, thereby making the flowers welcome during winter and spring.

To such perfection have hippeastrums been brought that one has every confidence in recommending the raising of plants from seed, such as is offered by our leading nurserymen, with the full assurance that the results obtained will demonstrate the care and skill bestowed upon this work of improvement by English seed houses.

As hippeastrums ripen their seed in autumn they may be sown at once; my own practice however, is to sow in January, using light soil and barely covering the seeds. The pots are plunged in a propagating case and kept close until germination takes place. As soon as the seedlings are large enough to handle they are potted off singly into three-inch pots and placed in a minimum temperature of 55 degs. Growth begins to be more rapid as the seedlings take to the soil, and when these pots are well filled with roots a shift into the flowering size is given, which may be 5-inch, 6¼-inch, or 7-inch pots according to the individual strength of the plants.

The soil requires to be made richer as each successive shift is given, so that in the first potting a compost of rough loam well enriched with manure from a spent mushroom bed, to which is added a small quantity of bone-meal, and one of the good fertilisers advertised in the GARDENERS' MAGAZINE, provides a suitable rooting medium. The majority flower the second spring from seed. The results are always more satisfactory and stronger plants are obtained when the pots can be stood for the greater part of their time over a medium bottom-heat, where, at the same time, the plants receive the maximum amount of sunlight, while the free use of the syringe among the plants and a certain humidity of the atmosphere within the house are conditions favourable to full development.

It is a good plan to occasionally examine the pots when in the hotbed, so that the roots may be prevented from entering the plunging material. When the growth has been satisfactory the first season the same treatment may be accorded the seedlings the second year as is given to the old flowering bulbs. By growing both batches together, the seedlings are gradually inured to a lower temperature, and as signs of ripening become apparent in autumn water must be gradually withheld and ultimately discontinued and the plants allowed to rest until there is fresh evidence of growth in spring.

From this time forward their treatment is in all respects that of established flowering bulbs.

In conclusion let me remark that hippeastrums are most accommodating plants for amateurs, even where facilities are absent for applying artificial heat throughout the year. By starting with fire-heat in spring and husbanding the sun's heat in a deep pit or frame throughout summer and autumn, the strongest plants will flower the second year and the remainder in the following winter and spring. Under these conditions the grower has less control over the plants, consequently the flowering is more erratic, and as often happens, the plants flower in succession over a period of five or six months, an advantage which those requiring only a few examples will readily appreciate.

THOMAS SMITH.

Walmsgate Gardens, Louth.

EARLY TOMATOES.

To obtain ripe tomatoes towards the month of February seed must be sown about August 10, and the plants grown as coolly and as sturdily as possible up to the middle of October, by which date they should be removed to their winter quarters, where a night temperature of 60 degrees to 65 degrees can be maintained, according to external conditions.

A low span house is preferable, running north and south, so that every gleam of sunshine, and a maximum of light can reach the plants while in flower, and also assist to ripen the fruit. Some people sow six weeks earlier, and have the fruit swelling by the date mentioned for bringing them indoors, but the ripening process is very slow during November and December. Plants flowering during the months just named must be kept dry overhead, and the flowers pollinated daily, and even then a satisfactory set is not always obtained should the weather prove sunless for some days, as it often does during winter.

We grow our tomatoes in ten-inch pots, and grow them as single stems, pinching out all side shoots and part of any leaf if it shades the fruit at all, but defoliation is never allowed. Weak liquid manure is applied to the roots now and again, but overfeeding is harmful in midwinter, neither is much root watering required unless the hot water pipes dry up the soil.

A sowing may now be made, putting two or three seeds in each three-inch pot, if but a dozen or so plants are required, reserving only the stronger one; keep them near the glass, and in a night temperature of 65 degrees. The formation of roots at this date is slow, and very little water necessary until a rough leaf is made. Transplant into 5½-inch pots as soon as they become fit, still keeping them near the glass in the same temperature, securing the plant to a stake, and lightly fumigating if white-fly appears. Shift them into ten-inch pots when ready, and if no proper house be at command a few plants can generally be accommodated in an early vinery or peach house, where ripe fruit may be expected during April and May.

J. MAYNE.

Bicton.

Verbenas. — Collections of verbenas seem to have become a thing of the past, yet the scarlet, white, and purple varieties are still grown for bedding. Stock plants that have been kept in a cool house through the winter may now be put into warmth, and they will soon provide cuttings. These succeed best in a good brisk bottom heat, and a rather low top heat. Not long after the cuttings are rooted they will require stopping, and the tops will make better cuttings than can be obtained from the old stock. When kept clean and healthy verbenas are very useful in the flower garden, but it often happens that they become infested with thrips and fly before being planted out, and then they rarely grow out of it. For mixed colours, seedlings are most satisfactory. Seeds sown about the middle of February produce good plants for summer bedding, and if a good strain of the compact varieties is obtained, these will give a mass of bloom throughout the summer and continue until frost sets in in the autumn.—T. B. FIELD, Ashwellthorpe Gardens.

THE GREAT SEA LAVENDER.

Statice latifolia is generally considered the finest of the hardy sea lavenders, and it certainly is well called the "great" sea lavender, by reason of its superiority in size to other members of the genus. The statices are essentially a family of sea-loving plants, as is shown by our wild British species, which grow in close proximity to the sea, or, at least, to salt water, and, therefore, a sandy soil, well exposed to the sun, may be regarded perhaps as ideal for these plants. As a matter of fact, however, the great sea lavender seems to thrive in any ordinary garden soil, and it grows in the greatest luxuriance with me in a heavy clay, receiving, like the rest of the border, liberal quantities of animal manure every year, with a dressing of basic slag to supply the phosphate and remedy the natural deficiency of lime in the soil.

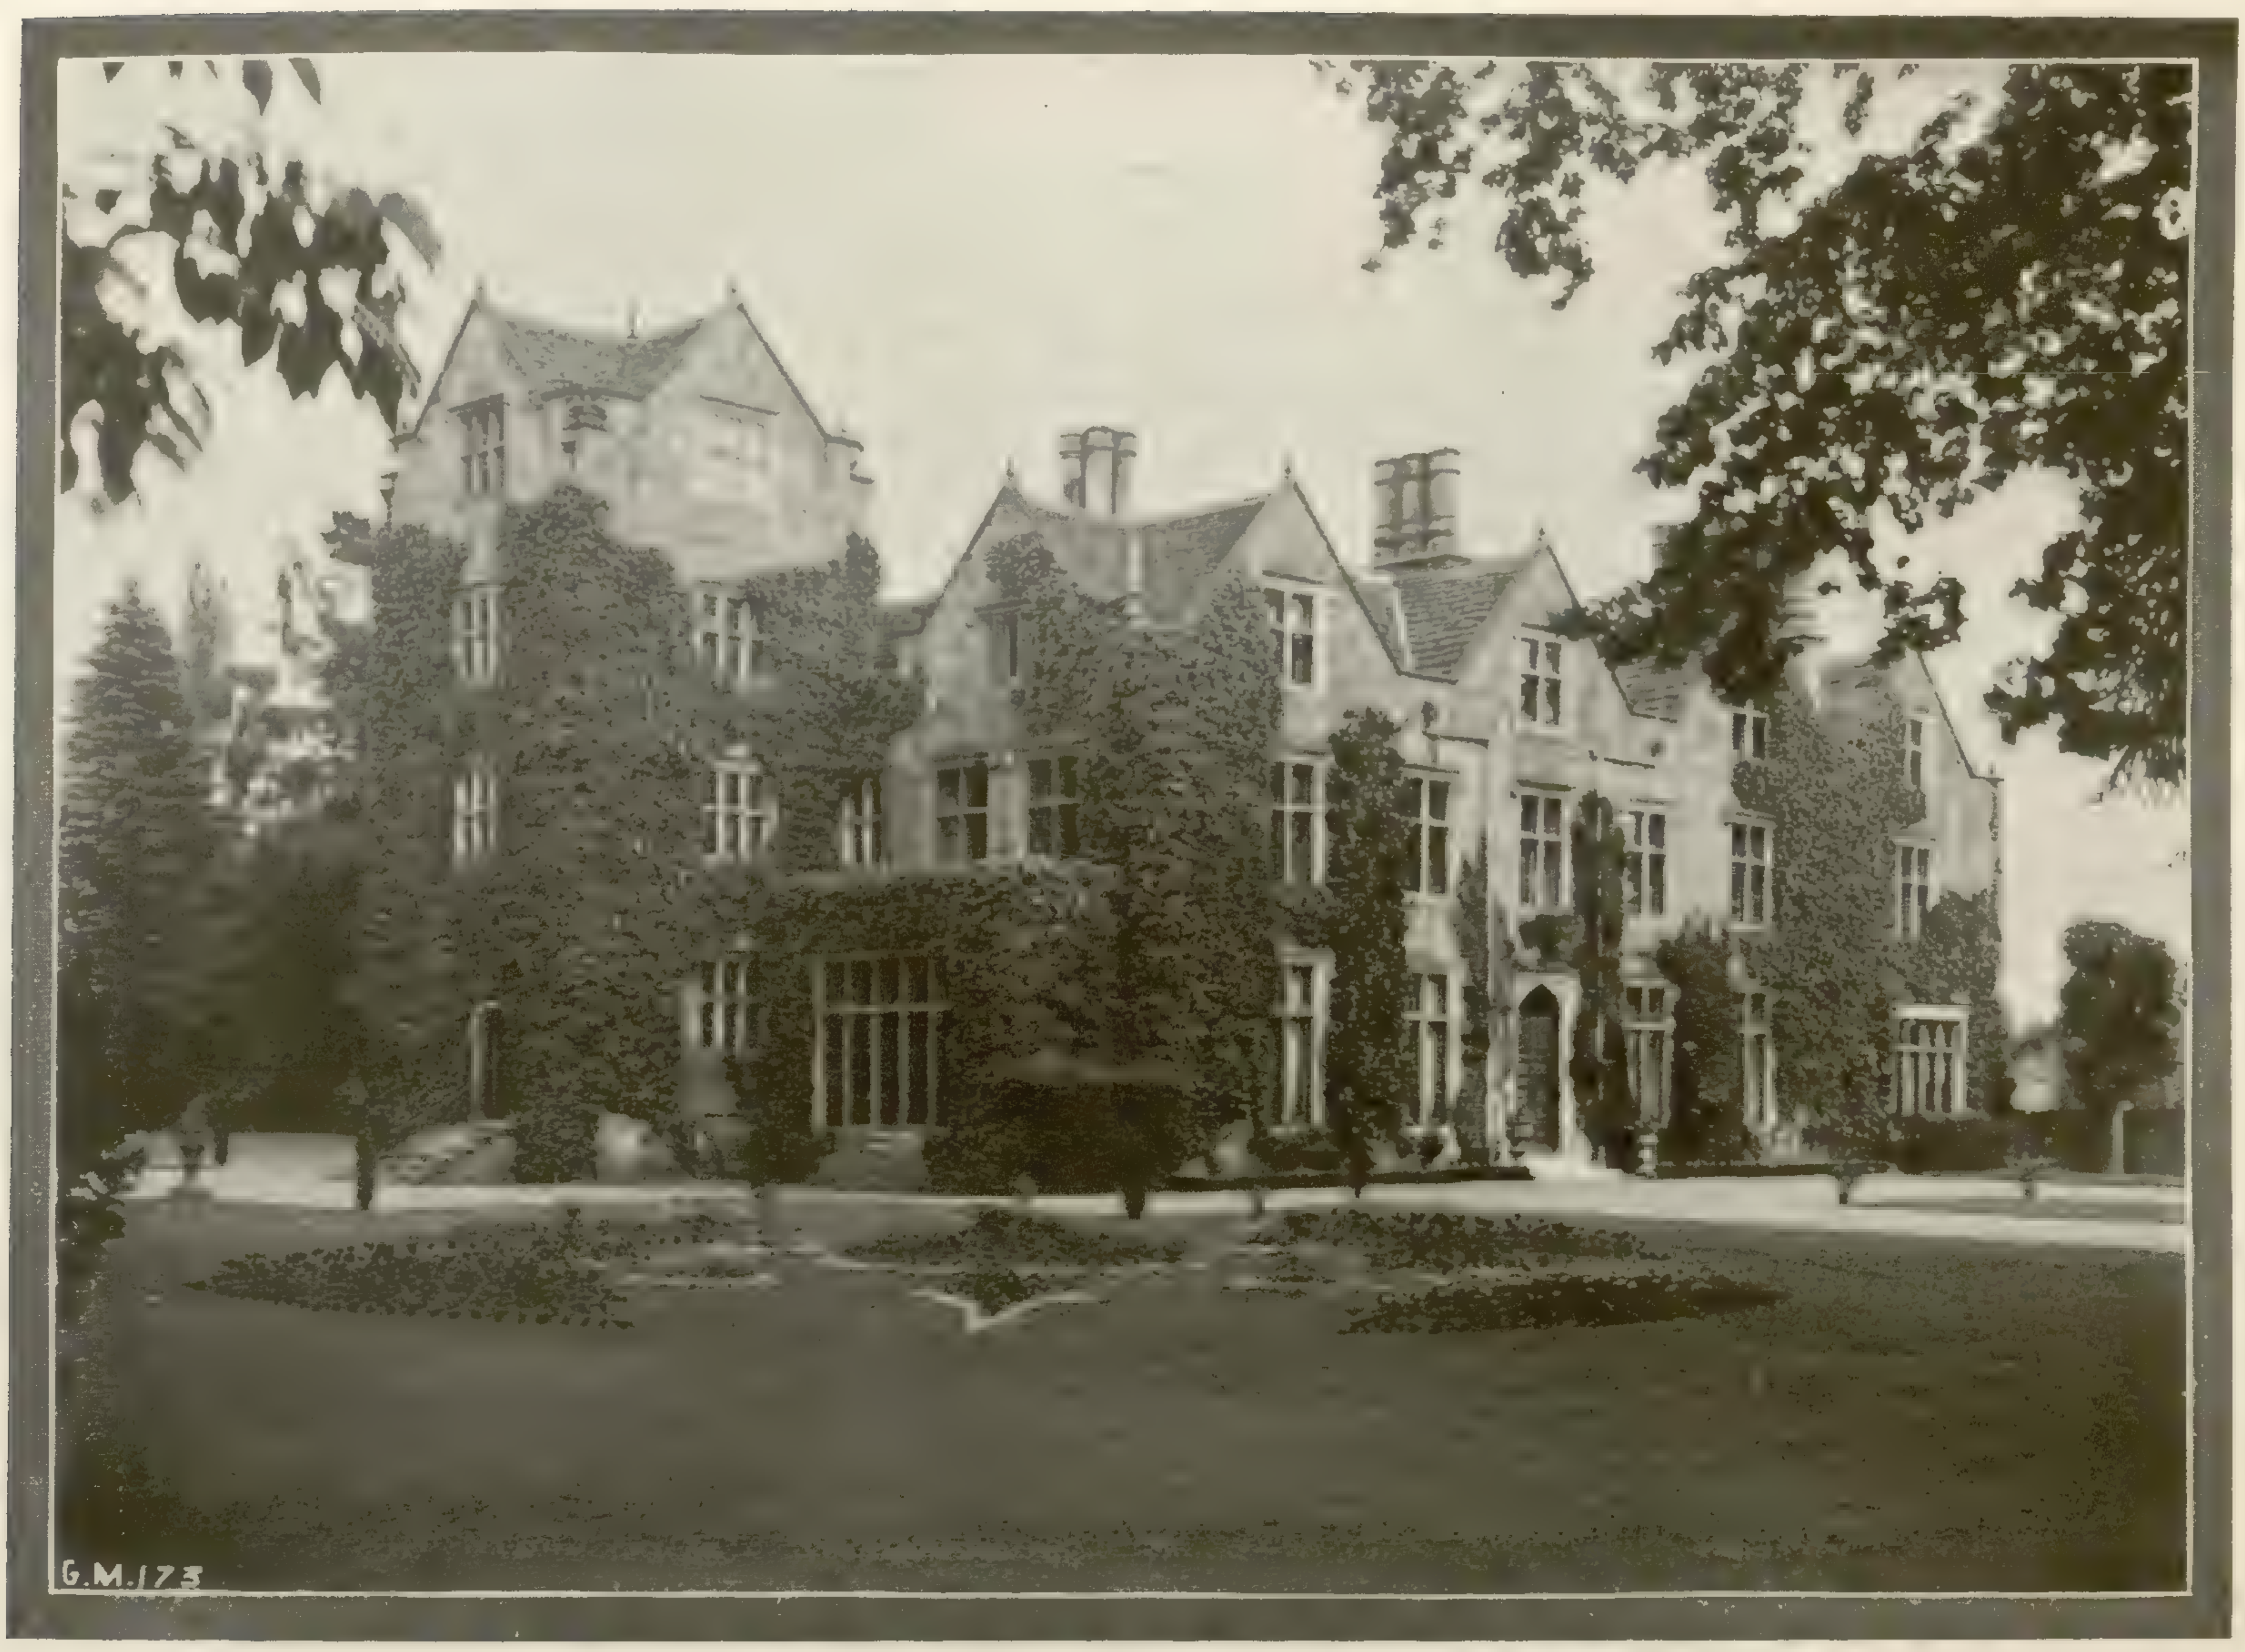
It is distinguished from all other sea lavenders with which I am acquainted by its very large shining leaves, which remain more or less green through the winter—unless very severe weather comes—thus forming a welcome plant in the mixed border, which is apt to present a rather dreary spectacle in the winter season. It sends up strong branching flowering stems, which bear a profusion of small lavender-blue flowers, forming a sort of blue haze when viewed at a distance. With many of the family these blue flowers, if cut as soon as they are open, persist, that is, dry up without much alteration of appearance, and so remain indefinitely. With this species, however, the flowers dry up and fall off after lasting in bloom a considerable time, leaving the white calyces, which are not ineffective for winter decoration when mixed with other similar things. If cut soon after the flowers come out they may persist to some extent, but do not retain much of their colour. At least, such is my experience, though it may only be due to unfavourable soil and an inland situation.

This sea lavender is very deep rooting, and consequently does not bear moving well, having a strong perpendicular tap-root of unknown length. It is, therefore, best to plant it where it may remain undisturbed for years. It may be propagated by taking side shoots with a little piece of root attached, these being put in pots with a little sand, and set in a frame or house. Any attempt to take up the plant and divide it may result in disaster. Seed may be obtained, but the seedlings are a long time before they make effective flowering plants, and as one does not usually want a large number of them, it is better to buy two or three plants and propagate from them if necessary. The placing of them in the mixed border needs a little consideration from the point of colour effect, as blue flowers do not "go" with everything, especially with those of a bright red, magenta, or purple colour.

For table decoration Statice latifolia comes in very useful, flowering, as it does, in August and early September, when Gypsophila paniculata is over, and the graceful feathery sprays of the Michaelmas daisies have not yet come on. Its blue colour is the more welcome, too, as so many of the late summer flowers are yellow—sunflowers, coreopsis, etc.

A final word as to planting. This perennial takes up a good deal of space in the summer with its large spreading leaves, and, therefore, it is advisable to use some of the space between the clumps for spring bulbs, as the leaves can be cut in at the approach of spring.

ALGER PETTS.



DENNE PARK: THE MANSION.

SOME HORSHAM GARDENS—I.

"In Sussex there is a pretty market town called Horsham, and near unto it a great forest, called St. Leonard's Forest," writes the compiler of a remarkable pamphlet, published in 1614, relating to "a monstrous serpent or dragon," that was said to have made its appearance in the big tract of woodland to the east of the town to the dismay of the inhabitants of the district. What was true at the beginning of the seventeenth century is hardly less so at the present time. There is still in Sussex a market town that is decidedly pretty, and known as Horsham, and there is also a large tract of land extending some miles eastward that on the maps is designated St. Leonard's Forest. This area is no longer "a vast and unfrequented place, heathie, vaultie, full of unwholesome shades and overgrown hollowes," as when the dragon was supposed to have its home within its solitude. It has long since been divided and much of it brought into cultivation, and where once brushwood and timber trees had undisputed sway there are well-planned estates, with stately mansions and extensive well-kept gardens that have long had a foremost position among the horticultural establishments of the United Kingdom. These are by no means the only gardening features of the Horsham district, for to the south, west, and north of the town are gardens of more or less importance, and within the borough are gardens innumerable that afford evidence of the strong love for flowers that exists among the residents.

Denne Park.

Denne Park, the ancient and stately residence of E. M. Eversfield, Esq., is within a comparatively short walk of the town; and its gardens, so long famous for their roses, afford much to interest whatever may be the trend of the taste of the visitor. Owing to the high ground on which the mansion and gardens stand a fairly stiff climb is necessary to reach them, but the walk is extremely pleasant, and affords several views of surpassing beauty. Not the least beautiful of these is that of the town nestling amid the trees in the hollow below.

The general style of the mansion, as will be seen from the accompanying illustration, is of the Stuart period, but the front is of more modern date, and quite in keeping with the older portions. Situate among trees of noble proportions, the mansion presents a stately appearance, and from the high ground on which it stands magnificent views are obtained over the North Weald, Leith Hill being the most conspicuous of the landmarks. The approach from the London and Worthing road is through a magnificent avenue of beeches, the length being over half a mile, and the trees equally remarkable for their large size and splendid development. The lawn on the side of the house facing the avenue is bounded by elegant gates and railings in wrought iron, and these are of much interest for they are not less than four hundred years old, and were made from iron smelted in one of the Sussex forests. Here we have evidence of Mr. Eversfield's taste for roses, as over the light and elegant railings climbing roses fling with unrestricted freedom their long and graceful branches, that when we had the pleasure of seeing them were enwreathed in their attractively-coloured blossoms. Especially attractive, on a wall to the left of the gateway, were large finely-flowered specimens of Marie Van Houtte and Caroline Kuster.

On the east side of the mansion is a wide expanse of lawn so admirably kept as to at once attract the attention of those who fully appreciate the charm of level, soft, and rich green turf. There are a few flower beds on this, as on the other side, to give colour to the scene without breaking up, as it were, the delightful open space; but the distinguishing feature of this part of the pleasure grounds is formed by the numerous finely-developed specimen trees. Here are cedars of Lebanon, whose wide-spreading branches suggest considerable age; a specimen of Wellingtonia gigantea, planted in 1859, that pierces the sky at a height of about one hundred feet, and examples of various cupressus and thuias of great height and perfect in their development. The deciduous trees are not less noteworthy, and chief among them is a weeping ash that rises to a height of thirty feet, and with its long flexile branches sweeping the lawn presents the appearance of an exquisite fountain of verdure.

Mr. Eversfield has long occupied a prominent position among amateur rosarians, and those who have seen the finely-developed roses from Denne Park at the exhibitions of the National Rose Society and elsewhere will not be surprised to learn that the rose garden forms a feature of much interest. This is situate a short distance from the mansion, and is so arranged that it does not come into view until the belts of trees that shelter the roses from the north and east winds are passed. The garden is open to the south and west, on which sides it is bounded by a fine old orchard, and in the sheltering belts of trees are numerous thuias, large in size and perfect in development. In accordance with the usual practice, the roses are grown in long narrow beds for convenience in giving the blooms the attention necessary to ensure perfect development. Standards, half-standards, and bushes are grown in due proportion; and as will be readily understood, the varieties include all the finest of those held in high estimation by the general body of cultivators for exhibition purposes. While not a separate department of the garden the roses are under the charge of a grower who devotes his whole time to them, and, like Mr. Harris, the able head gardener, is not less enthusiastic than he is skilful.

LEONARDSLEE: SUBTROPICAL VEGETATION.

The kitchen garden lies to the south or south-east of the mansion, and is equally remarkable for its antiquity and the skill with which modern methods of culture are carried out. The substantial walls with which the garden is enclosed are said to be a thousand years old, and there is nothing to give rise to a difficulty in accepting the statement. But whatever may be their age, they are well clothed with fruit trees of the most approved kinds. Alongside the intersecting walks are fruit trees and herbaceous plants in variety, all of which contribute their share to the interest associated with a visit to these fine old gardens. The plant and fruit houses are not less interesting in their way than are the outdoor departments, but it must suffice to say that they bear the impress of the skill that is evident on all sides.

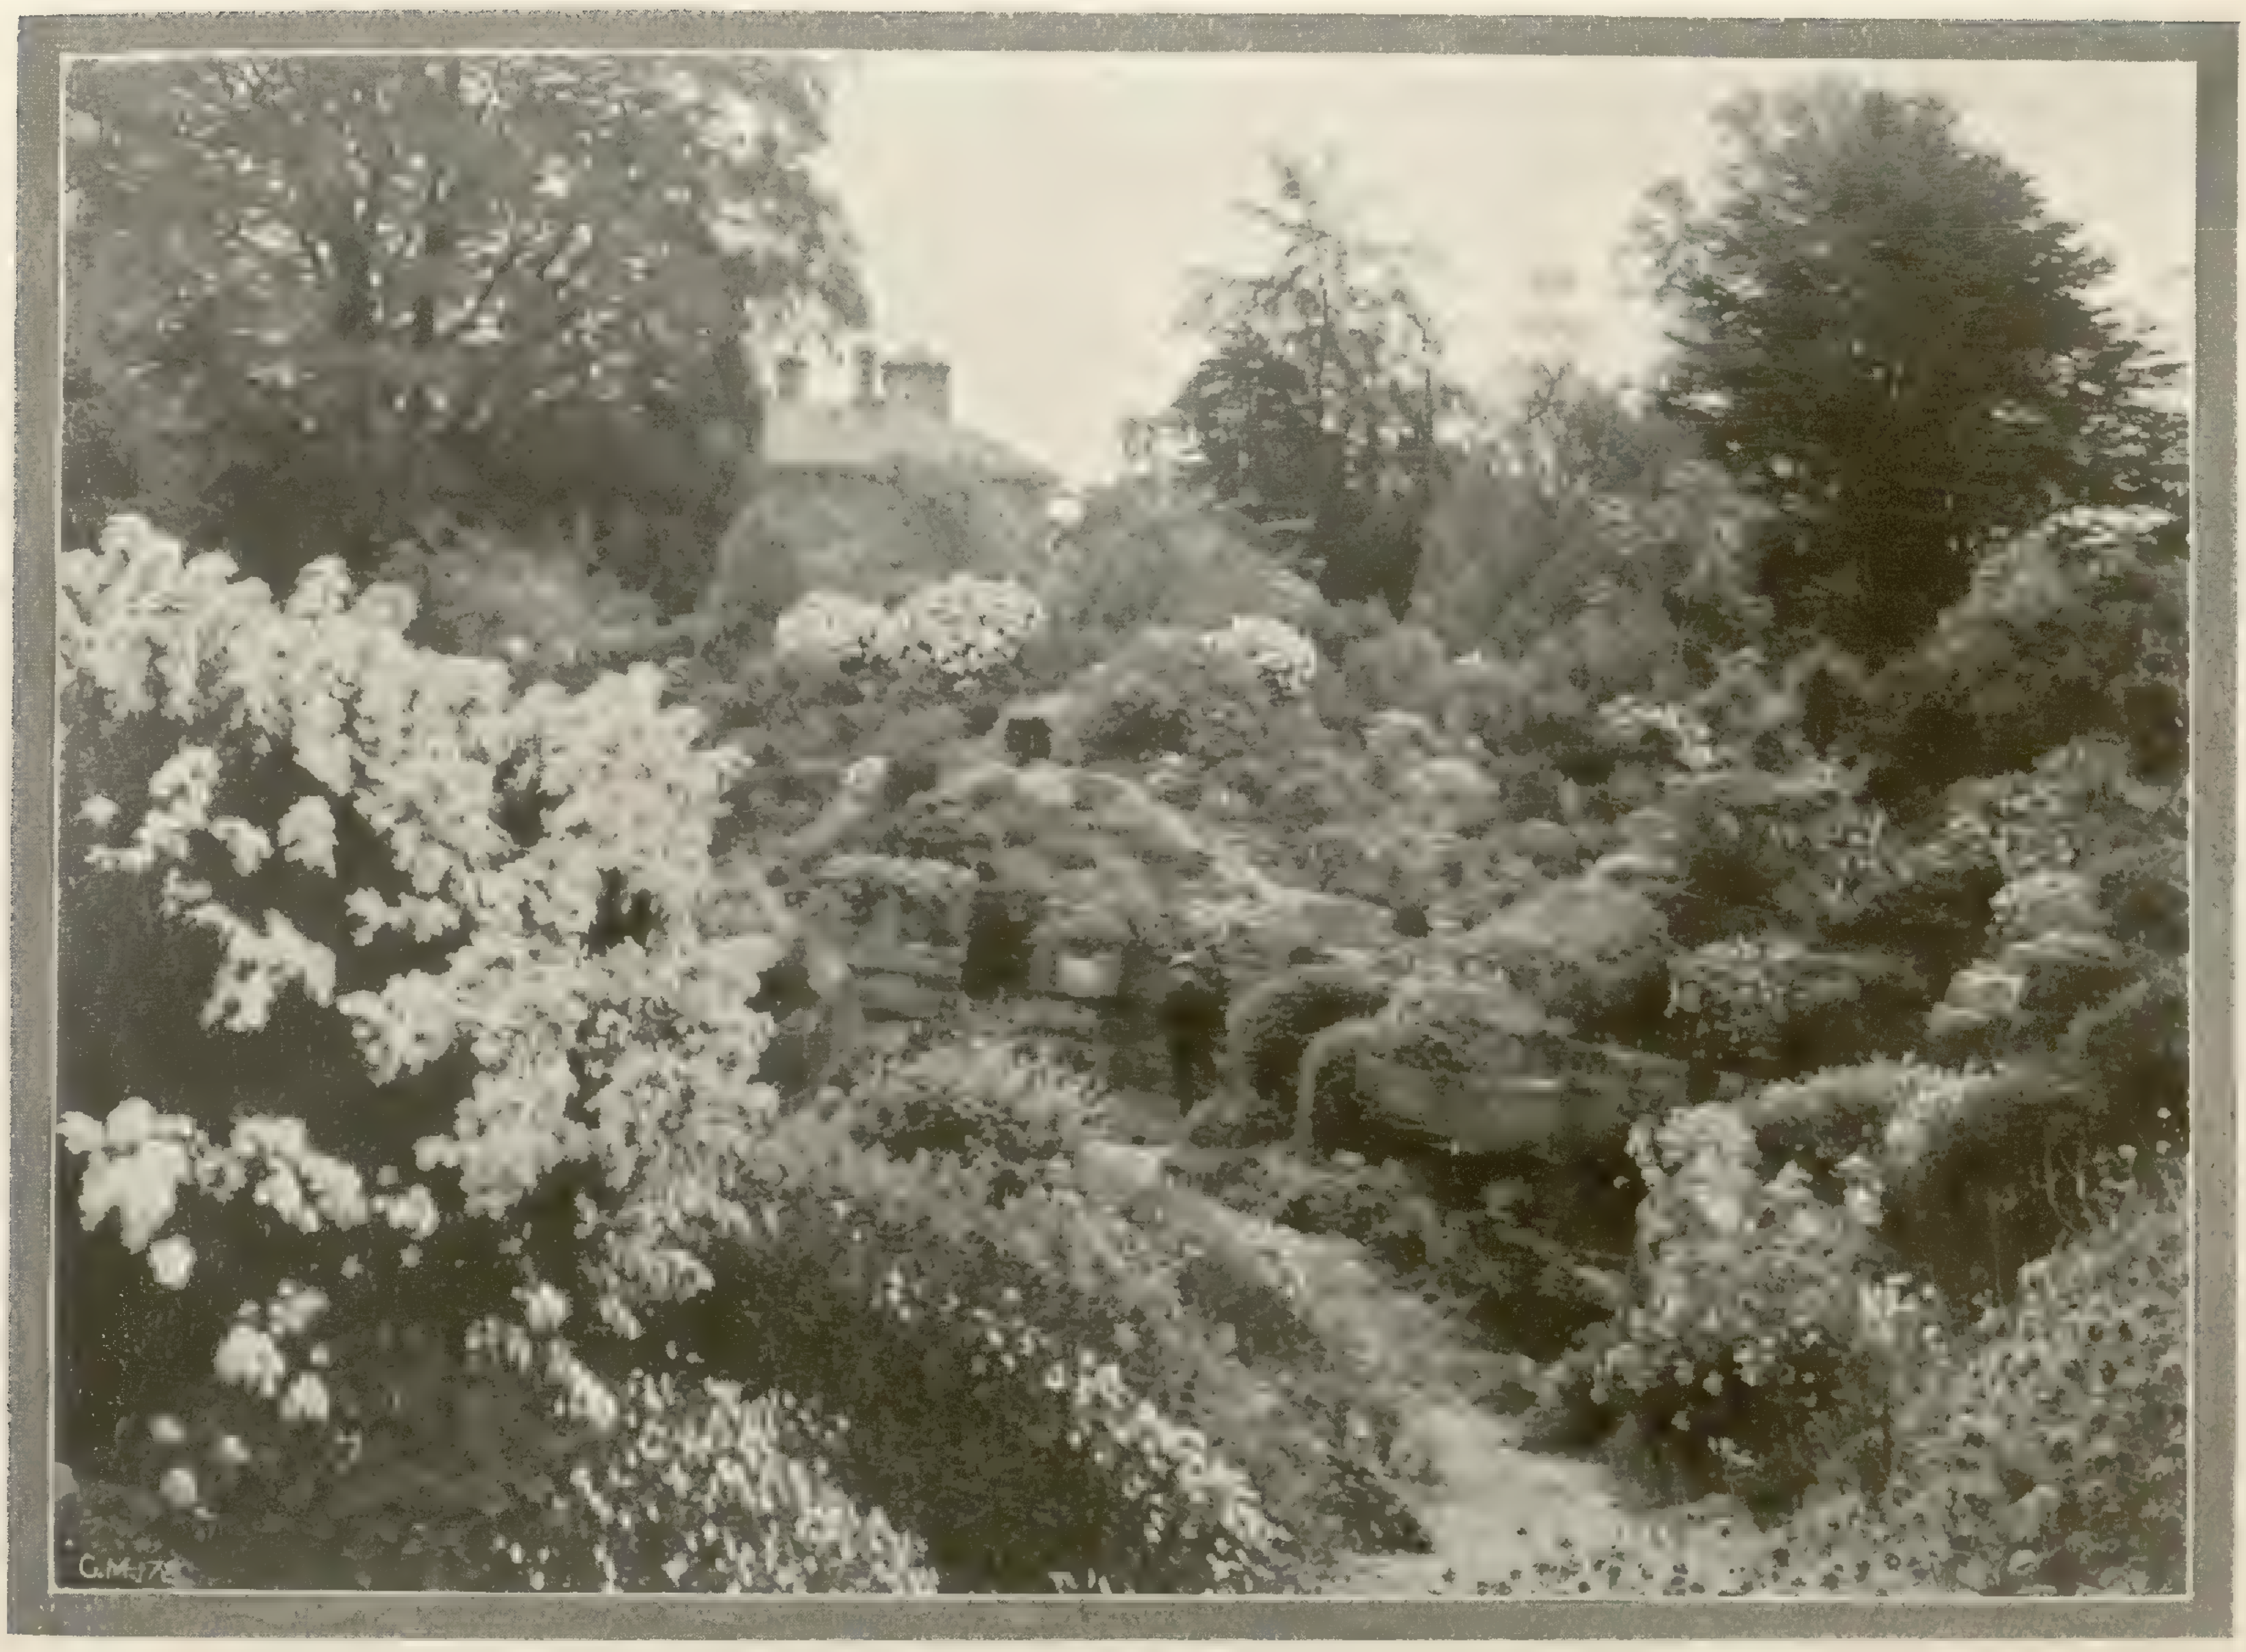
Leonardslee.

To the general body of horticulturists Leonardslee, the seat of Sir Edmund Loder, Bart., is known by the many interesting plants that have been sent from them to the exhibitions and meetings of the Royal Horticultural Society. These will have served as an indication of the exceptional interest that is associated with them, and their richness in plants that are more or less rare. They will have done much to make the gardens known, but a personal visit only will enable one to have an adequate idea of their extent, their interest, their characteristics, or their wondrous beauty. This fine seat is situate in St. Leonard's Forest, some four or five miles to the south of Horsham, and the walk or drive there abounds in points of interest, and as the road occupies high ground for the greater part of the way a succession of views is obtained of scenery of a charming character. Those who have an opportunity of visiting the gardens of Leonardslee will be well advised in driving out. Their area is enormous, they give plenty of stiff climbs, and there is so much deserving of attention that the strongest athlete might well be excused were he to show signs of a slackening of interest after a few hours' exploration, if previously he had had a long walk. Yes, the visitor who would enjoy to the full the many attractions should come fresh—let it not be said to his task, for that word would be inappropriate; but a leisurely inspection of these wondrous gardens.

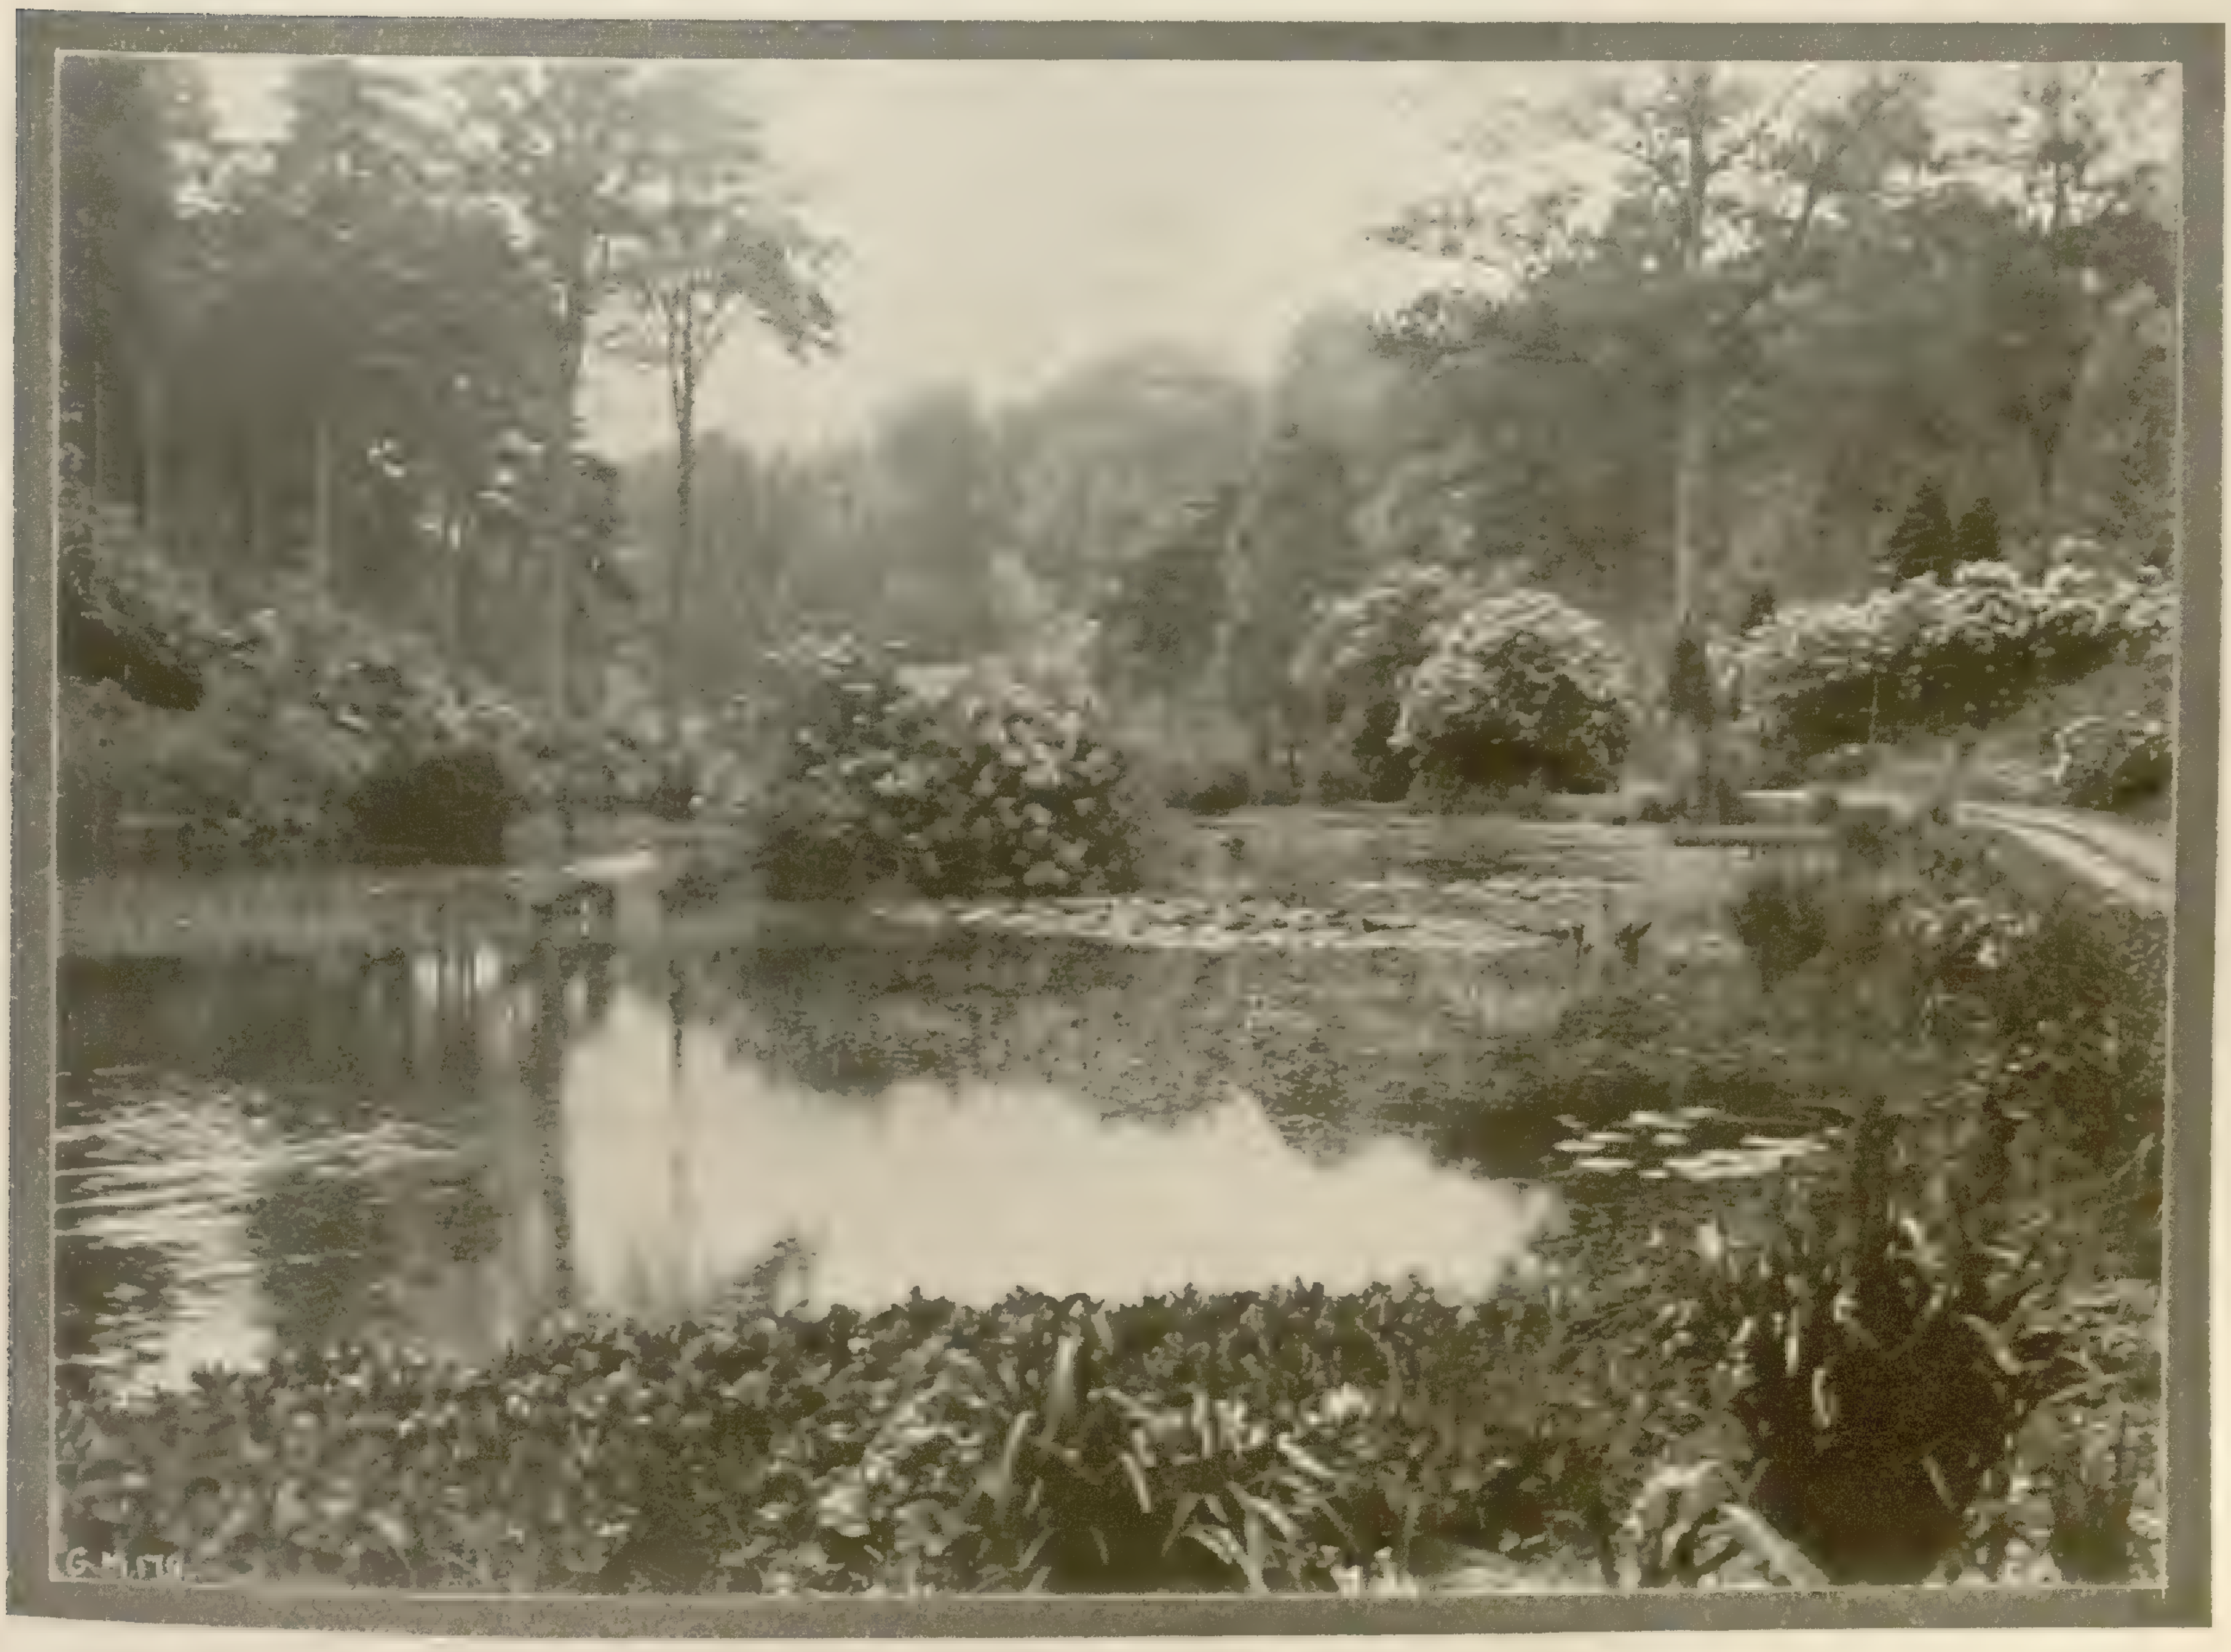
So distinct in character from the horticultural establishments with which we are generally acquainted are the gardens of Leonardslee, that it is not an easy matter to convey a clear idea of their general scope or of their distinctive characteristics. Let the reader imagine for a moment a deep valley with a sharp slope on either side extending for a mile or so. Then in imagination clothe the greater part of the slopes with beeches and oaks, larches and pines, and other trees that usually have a place in the English woodland. Having accomplished this, proceed, still in imagination, to beautify the open spaces on the slopes with the choicest of shrubs and the most beautiful of hardy perennials: clear away the greater part of the brushwood from beneath the trees and replace it with thousands of mollis and Ghent azaleas, and rhododendrons innumerable. The reader, if he is endowed with such powers of imagination as will enable him to accomplish these things, will have obtained a rough idea of the general scope of the gardens. But before it is possible to realise their charms and interest many details will have to be filled in, and to accomplish this successfully one had need have the intimate knowledge of plant life possessed by their owner.

The trend of the valley is from north-west to south-east, and along the lower parts flows a stream of water, which has been expanded into a series of lakes, several with an area of eight or nine acres. These and the connecting stream provide in their water and on their banks a home for one of the most comprehensive collections of moisture-loving plants that has yet had a place in a private garden. The mansion occupies a commanding position on the south-west side of the valley, and is surrounded by lawns and pleasure grounds that, while free from any trace of wildness, are highly picturesque and without a trace of formality. On the eastern front are tastefully disposed groups of trees and shrubs of the choicest description, the finest of the green and variegated hollies, berberis, and rhododendrons predominating.

In a sheltered position on the eastern lawn is a tastefully arranged enclosure devoted to roses. This is known as Lady Loder's rose garden, for herein her ladyship evinces her skill in rose culture, and indulges her taste for the fragrant blooms in their diversity of form and colouring. It would appear from the evidence to be found in the rose garden that Lady Loder does not restrict her appreciation of roses to any one section. Hybrid perpetuals, hybrid teas, and teas all represented in bush and standard form; and on pillars, arches, and other supports ramblers and climbers display their charms. Near the south-east corner of the mansion is a tulip tree of such remarkable proportions that it is regarded by the leading authorities as one of the finest trees of its kind in the country. When measured last spring the height was found to be ninety-seven feet. On the terrace, at the north-east corner of the mansion, is probably the finest outdoor camellia in England, or for the matter of that the finest specimen, whether under glass or in the open. Occupying one of the most exposed positions in the garden, this specimen has assumed the form of a round-headed bush, has a height



LEONARDSLEE: VIEW IN ROCK GARDEN.



LEONARDSLEE: WOODLAND LAKE.

of twenty feet, and a circumference of sixty feet, and was bearing when it first came under my notice, in the spring of 1907, 10,000 blooms. Ten thousand blooms is a large number to be borne by one specimen, and although based on an estimate, there was no great difficulty in accepting the number, for the whole of the growths, to a depth of about two feet from the outer surface, were simply wreaths of flowers. Some day my readers will probably have an opportunity of seeing a photographic reproduction of this unique camellia bush.

Right and left of the Mansion are long borders devoted to choice shrubs, intersected by a central walk, and enclosed between sheltering belts of evergreen and deciduous trees and shrubs of robust habit. Growing with great vigour in the enclosure on the right, or south side of the mansion are a considerable number of camellias, ranging from ten to twelve feet or more in height, in the most vigorous condition, and annually producing a profusion of flowers. Among them was the Double White, and it was interesting to note the purity of its flowers. These borders are not alone of interest for their camellias, as within them are finely furnished examples of Chamaerops Fortunei, rising to a height of twenty feet or more, great masses of the New Zealand flax, huge specimens of Aralia Sieboldi, and other subjects that suggest a warm corner in a Cornish or Devonshire garden. Here also are several of the most rare and beautiful of the Himalayan and other rhododendrons, notably the unique specimens of R. Thomsoni.

The corresponding border on the north-east side of the mansion is a short distance therefrom, and is approached by a broad walk, with continuous arches of roses on either side, and through a strip of lawn that in the spring season is given up chiefly to daffodils. On the grass, at short distances apart, several hundred small beds have been formed, and these are filled with choice daffodils, forty to fifty bulbs of one variety in each. The effect is much the same as that produced by daffodils springing from the grass, with the advantage that Mr. Cook is able to lift the bulbs and deal with them in such manner as may be considered desirable. About a million of narcissi are grown. In the enclosed borders beyond may be found large clumps of such choice daffodils as King Alfred and White Queen, numerous rare rhododendrons of comparatively low growth, and many other choice shrubs that bloom early in the year. In another enclosure immediately behind this are other choice rhododendrons, notably the numerous examples of R. Thomsoni, which in April produce a fine display of brilliant crimson flowers.

Proceeding onwards, through the well-wooded slopes that are practically a continuation of the gardens north-west of the mansion, we have a choice of paths. There is, however, no occasion for perplexity as to which to take, for alongside each of them there is plenty to charm the eye and interest the mind. These slopes form a huge garden, for in the great open spaces are huge rhododendrons, associated, it may be, with palms of varying heights, some being of quite exceptional proportions. In the smaller clearings are big groups of the finest of the Himalayan and other rhododendrons, of camellias, Indian azaleas, and other shrubs, not usually seen out of doors, and so arranged as to suggest that they are part of the native flora. In suitable positions also are the stronger-growing rambling roses, loosely trained to lofty poles until they reach the top, when they are allowed to grow naturally, according to their own sweet will. Continuing down the slopes until the stream is reached that flows along the valley, a spot is found that is given over chiefly to flowers that belong to the spring season, and a more exquisitely beautiful floral picture it would be difficult to conceive than that formed by the flowers of the thousands of iris, polyanthuses, primroses, etc., that have been naturalised. The slopes on the left or north-east side of the valley have been enriched by many thousands of hardy azaleas and rhododendrons, and the brilliant display that is annually made is one that lingers long on the memory.

The chain of lakes and pools that extend through the valley forms a water garden probably unequalled in its area, and certainly not surpassed in the facility it affords for the cultivation of plants that thrive in and contiguous to water. An enumeration of the moisture-loving plants grown at Leonardslee would probably exhaust the list of those available in this country, and include not a few that are rarities. The general character of the water garden is shown in two of the accompanying illustrations, and from these is will be seen that the stately gunneras and the elegant bamboos have been freely utilised in the planting of the margins. One might linger long enjoying the charms of the varied forms of plant life growing in and around the lakes and pools, but the rock garden has yet to be seen, and it is not possible to do more than have a mere peep at the great breadths of the North American pitcher plants (Sarracenia purpurea) that luxuriate in the bog on the sunny slopes not far from the unique specimen of Picea morindoides, of which an illustration was given in the GARDENERS' MAGAZINE of January 18.

The rock garden is undoubtedly one of the finest of its kind, and constitutes a feature immensely interesting and highly attractive. It is spacious enough to provide accommodation for a comprehensive collection of alpines, and it is so arranged as to admit of the several kinds having the aspects and soils most favourable to a healthy growth. An illustration is given herewith of one part, but half a dozen pictures would no more than suffice to show its general character and the vigour of growth of the numerous alpines that occupy the various slopes, and the freedom with which they yield of their wealth of beauty. To particularise is not now possible, but it must be said that the collection of alpine pinks, which occupies one of the largest and sunniest of the slopes, forms an extremely beautiful feature, and that the dwarf coniferous trees, placed in suitable positions, materially enhance the general effect.

Of the large collection of Himalayan rhododendrons under glass, in which Sir Edmund Loder and his able gardener, Mr. A. W. Cook, take special interest; of the plant and fruit houses, and of the admirably managed kitchen and fruit gardens it would be pleasant to write, but space forbids. It will, however, be readily understood that under the charge of so skilful a gardener as Mr. Cook everything represents culture of the highest class. This brief account would, however, be wanting in completeness were it not said that Sir Edmund Loder is not less keenly interested in animal than in plant life, and that in the enclosures contiguous to the mansion are light-footed gazelles and ponderous kangaroos, and that one of the lakes in the valley is given up to beavers, where they are allowed to display their skill in cutting down trees and dam making without let or hindrance.

Holbrook Park.

Of a quite distinct character from either of the foregoing is Holbrook Park, the charming residence of H. Alan Scott, Esq., which lies some three miles distant to the north-west of the town. The dominant features of the gardens are the wide-spreading lawns, the stately trees, and the profusion of garden roses. From the garden front of the mansion the wide expanse of lawn stretches away in the distance, if not as far as the eye can reach, far enough to suggest almost illimitable space. To the right and left of this magnificent stretch of turf are fine belts of trees, in which are oaks and beeches of exceptional magnitude, and in suitable positions are groups of rhododendrons in the rudest of health, with flower beds of large size and tastefully furnished.

There are two rose gardens, the smaller of which is formed in the angle of the mansion, with sunken beds, as herewith illustrated, and devoted chiefly to tea-scented varieties and hybrid teas. The other is on the far side of the stream, shown in the second of the two illustrations, and here strong-growing varieties are well represented, and allowed to grow more or less naturally. This rose garden extends some distance back from the water, and is bounded on the far side by a hedge of the popular Crimson Rambler that has probably no equal. It has a length of many yards, and is nine feet in height, and when the plants are in bloom there is so brilliant a display of colour as to startle one by reason of its intensity. A noteworthy feature of these gardens is the long pergola clothed with rambling roses, of which a glimpse is seen on the left-hand side of the illustration of the water scene. The framework is of rough oak branches, and the roses grow with so great a vigour and bloom with such profusion as to prove to demonstration that Mr. Dancy, the able gardener, fully understands their requirements. As the pergola is of great length, and extends over two distinct levels, it has an appearance very different to that presented by pergolas on ground that is level throughout their whole length, but it is pleasing nevertheless, and is naturally much admired by visitors, especially so by those who see it in the season of roses.

On the other, or outer side of the hedge of Crimson Rambler rose that forms one of the boundaries of the larger rose garden there is an extensive orchard, in which the most approved kinds of the fruits usually grown in standard form are admirably represented. This orchard is intersected by a fruit pergola nearly two hundred and fifty feet long, which is approached through an opening in the rose hedge, and is well furnished with cordon apple and pear trees. As it is hoped that an opportunity will occur at no distant date for making further reference to the pergola, it will suffice to say that the trees present a most attractive appearance when in bloom, and also when the fruits are approaching their full development. On the east side of the orchard about half an acre is planted with choice daffodils, and as the conditions are favourable to their full development they annually produce a beautiful display.

In the fine old kitchen garden there is much to interest, for Mr. Dancy is especially well versed in the art of vegetable culture, as exemplified by his success in many a keen contest, more particularly with onions. Here we find large breadths of the vegetables in general use in the best possible condition, and on one side a long border of hardy herbaceous plants. In a corner, with yew hedge for a background, there is a selection of the finest of the delphiniums, these being highly effective by reason of the high quality of the varieties and splendid development of their spikes.

Within the kitchen garden are numerous plant and fruit houses, all of which are evidently fully utilised in the cultivation of the several subjects to which they are devoted. Figs in pots are, it was noticed, grown with much success, as also is the loganberry in the open. Not less noteworthy is the wire trellis, over which red currants are trained, for the crop annually obtained is so heavy as to surpass those produced by bush trees occupying a greater space. **GEORGE GORDON.**

⁂ The second of the two illustrated articles on noteworthy gardens in the Horsham district will be given in our next issue (February 15).

LOOKING BACKWARD.

In these days of progress it is well for one sometimes to look back over the past and note the various changes that have taken place. I was reminded the other day, by a letter that I received from an old journeyman of mine, who is now in business for himself, that it was in 1875 he first came to live with me. A third of a century ago! What changes have take place since then! When I look back on my early days and think of the difference there was in the treatment of young men then and now it almost makes me wish I had not been born so soon.

In those days there was no electric light in the bothy for the young men to study by, nor bathroom where he could take a plunge after a hard spell at stoking. In many instances the rooms were ill-lighted, cheerless, damp, and situated at the end of the stoke-hole or potting shed, where all the fumes of sulphur entered, for the only means of approach was through such places. No wonder then that the germs of rheumatism early settled in one's bones. The light provided, in many instances, was so meagre that one was often glad to resort to the stoke-hole, where, by the aid of the fire, sufficient light was provided whereby one could read of the doings in other places. Gardening papers in those days were not so plentiful as they are now, and the GARDENERS' MAGAZINE, though the oldest, was by no means so popular as it is at the present time, for during recent years this paper has undoubtedly become the best of all the gardening periodicals published.

It was by the aid of the stoke-hole fire in a noble Duke's establishment that the writer was enabled to master the most difficult problems in Euclid during the long winter evenings many years ago. The bothy had ground for the floor, and was approached first through the potting shed, then across a plank over the boilers, through another shed to the bothy door, the only air and light that was admitted being by this means, as there was no window in the room. As the days lengthened the work became more arduous, the hours of labour during the summer months were not restricted, and there was no pay for overtime. Often when one went in to tea at a late hour, before tea was presentable it was necessary to climb some tree to procure dead wood to make a fire. There were no half days off on a Saturday then; one was obliged to work from Monday morning until Saturday night, and if a half day were asked for to go and see some neighbouring garden, the time granted had to be made up. Going to see gardens in those days was by no means an easy task, as the whole journey had to be undertaken on foot; there were no bicycles then, and third-class trains were like stars on a stormy night—few and far between.

Such then were those "good old times" that some would have us go back to, the times when young men in the garden used to slave the whole week, Sunday included, for a pittance of 12s. a week. In those days, too, very few were allowed to enter the bothy who could not pay a premium to the gardener, and as in some instances this could not be provided by his friends, 2s. per week was stopped out of the man's wages, and he had 10s. to clothe and feed himself.

LEONARDSLEE: JAPANESE BRIDGE AND WATERSIDE VEGETATION.

Times have changed since then, and in most places comfortable lodgings are provided, though still, in many gardens, there is much to be desired. To procure the best and most respectable young men some inducement should be held out to give them more interest in their work. Surely a foreman in a large establishment is worth as much as an ordinary bricklayer or carpenter? But his pay does not amount to the same, and there is no reason why the young men in the gardens should work overtime without being paid any more than they should in any other walk of life. In many ways young men in the gardens are better off now than formerly. There is not the constant drudgery with the watering pots, as in most places there is now an ample supply of water, and one man can do with hose that which in days gone by would take several to perform. When water had to be carted from a distance it was but sparingly used, and in some instances many crops had to take their chance.

Gardening in those days was quite different to now. Hard-wooded plants were all the rage. What has become of those fine specimens of Cape heaths and pimelias that graced the show tents? No novice could grow such plants, yet they were grown without the aid of hot-water pipes, the old flues then being the chief means of heating. How many young men of the present day have had to strip and work in a pine stove? Not many of them would known anything about such work. Cheap carriage and differences in taste have brought about quite a revolution in gardening, as in other things; but in looking backward one is glad to find that with the progress of time there is also an advance in wages, and though, as a body, the same class of young men may not enter the craft as formerly, there are still some fine young fellows following our most ancient and useful calling. **RUSTICUS.**

BEST PLANTS FOR GREENHOUSE.—Nearly 300 pages are devoted to the description, propagation, and culture of the best flowers and plants for the greenhouse in THE AMATEUR'S GREENHOUSE, by T. W. Sanders, price 5s. net, or by post 5s. 6d., from W. H. and L. Collingridge, 148, Aldersgate Street, London.

ARAUCARIAS.

The cultivated species of araucaria are characterised by exceeding beauty of form, but, with two or three exceptions, are not sufficiently hardy to live an out of door life in this country. Araucaria Cunninghami and A. Bidwilli appear fairly happy in those genial parts of the country that boast a fairly equable climate, but it is very doubtful whether they will settle down as naturalised British subjects with a good grace. In all probability they would come to grief in the event of a severe winter unless well and very carefully protected.

The monkey puzzle, Araucaria imbricata, is certainly one of the most widely known subjects, and, speaking generally, does well over the greater part of the British Isles. It is true that most miserable and dilapidated specimens are met with very frequently, and these failures may be traced to a combination of unfavourable circumstances — the position being exposed and wind-swept, and consequently atmospherically dry, as compared with a secluded nook or corner, the evil being aggravated by very porous soil and inattention to artificial watering in times of drought. Shelter and a moist root run are the keynotes to success in the cultivation of this very distinct species, whose native habitat is the mountainous districts of Chili.

A. braziliana, as its name implies, hails from Brazil, and is scarcely worth attention, being of ungainly and straggling growth. From New Caledonia we get A. Balsamæ, which is exceedingly attractive in its young state, but it develops a straggling and undesirable habit with age. Grown in pots it is of great decorative value, and the same remark applies to all the species, the more tender of which should be grown to form handsome and imposing specimens for central groups in the conservatory or temperate house. When planted out under these conditions they flourish amazingly, and they may also be very successfully grown in large tubs, and in this case they may be utilised to play their part in the sub-tropical arrangement in the outside garden in summer.

A. Bidwilli and A. Cunninghami, already mentioned, are both distinctly handsome, but to have them at their best they must be cultivated under glass in this country, and these remarks are applicable also to A. Cooki, which is characterised by its columnar habit of growth. It is gratifying to know that nearly all the species are now met with in good gardens, and it is difficult to explain why they were to a great extent ignored over a long period.

The Norfolk Island pine, A. excelsa, has become one of the most popular of market plants, and enormous quantities are grown in the great trade establishments. Small wonder that they find a ready sale, seeing how beautiful they are in pots. Until recently I was under the impression that the vast majority were raised from seeds, but I am told by a large grower that 90 per cent. are raised from cuttings; also that the habit of growth, or arrangement of branch, is very different to that of plants grown from seeds. The difference lies in the fact that the tiers of branches are about three inches apart in the former, and are produced in this way, or at a slightly greater distance, over a couple of years or more, while in the latter they are divided by from fourteen to twenty inches of stem even in a young state, and consequently are vastly less ornamental and attractive than plants from cuttings. There are several varieties of A. excelsa, but neither approach the type in beauty or general utility.

Walter H. Aggett.

HOLBROOK PARK: SUNK GARDEN OF TEA ROSES.

THE VALUE OF THE LAURUSTINUS.

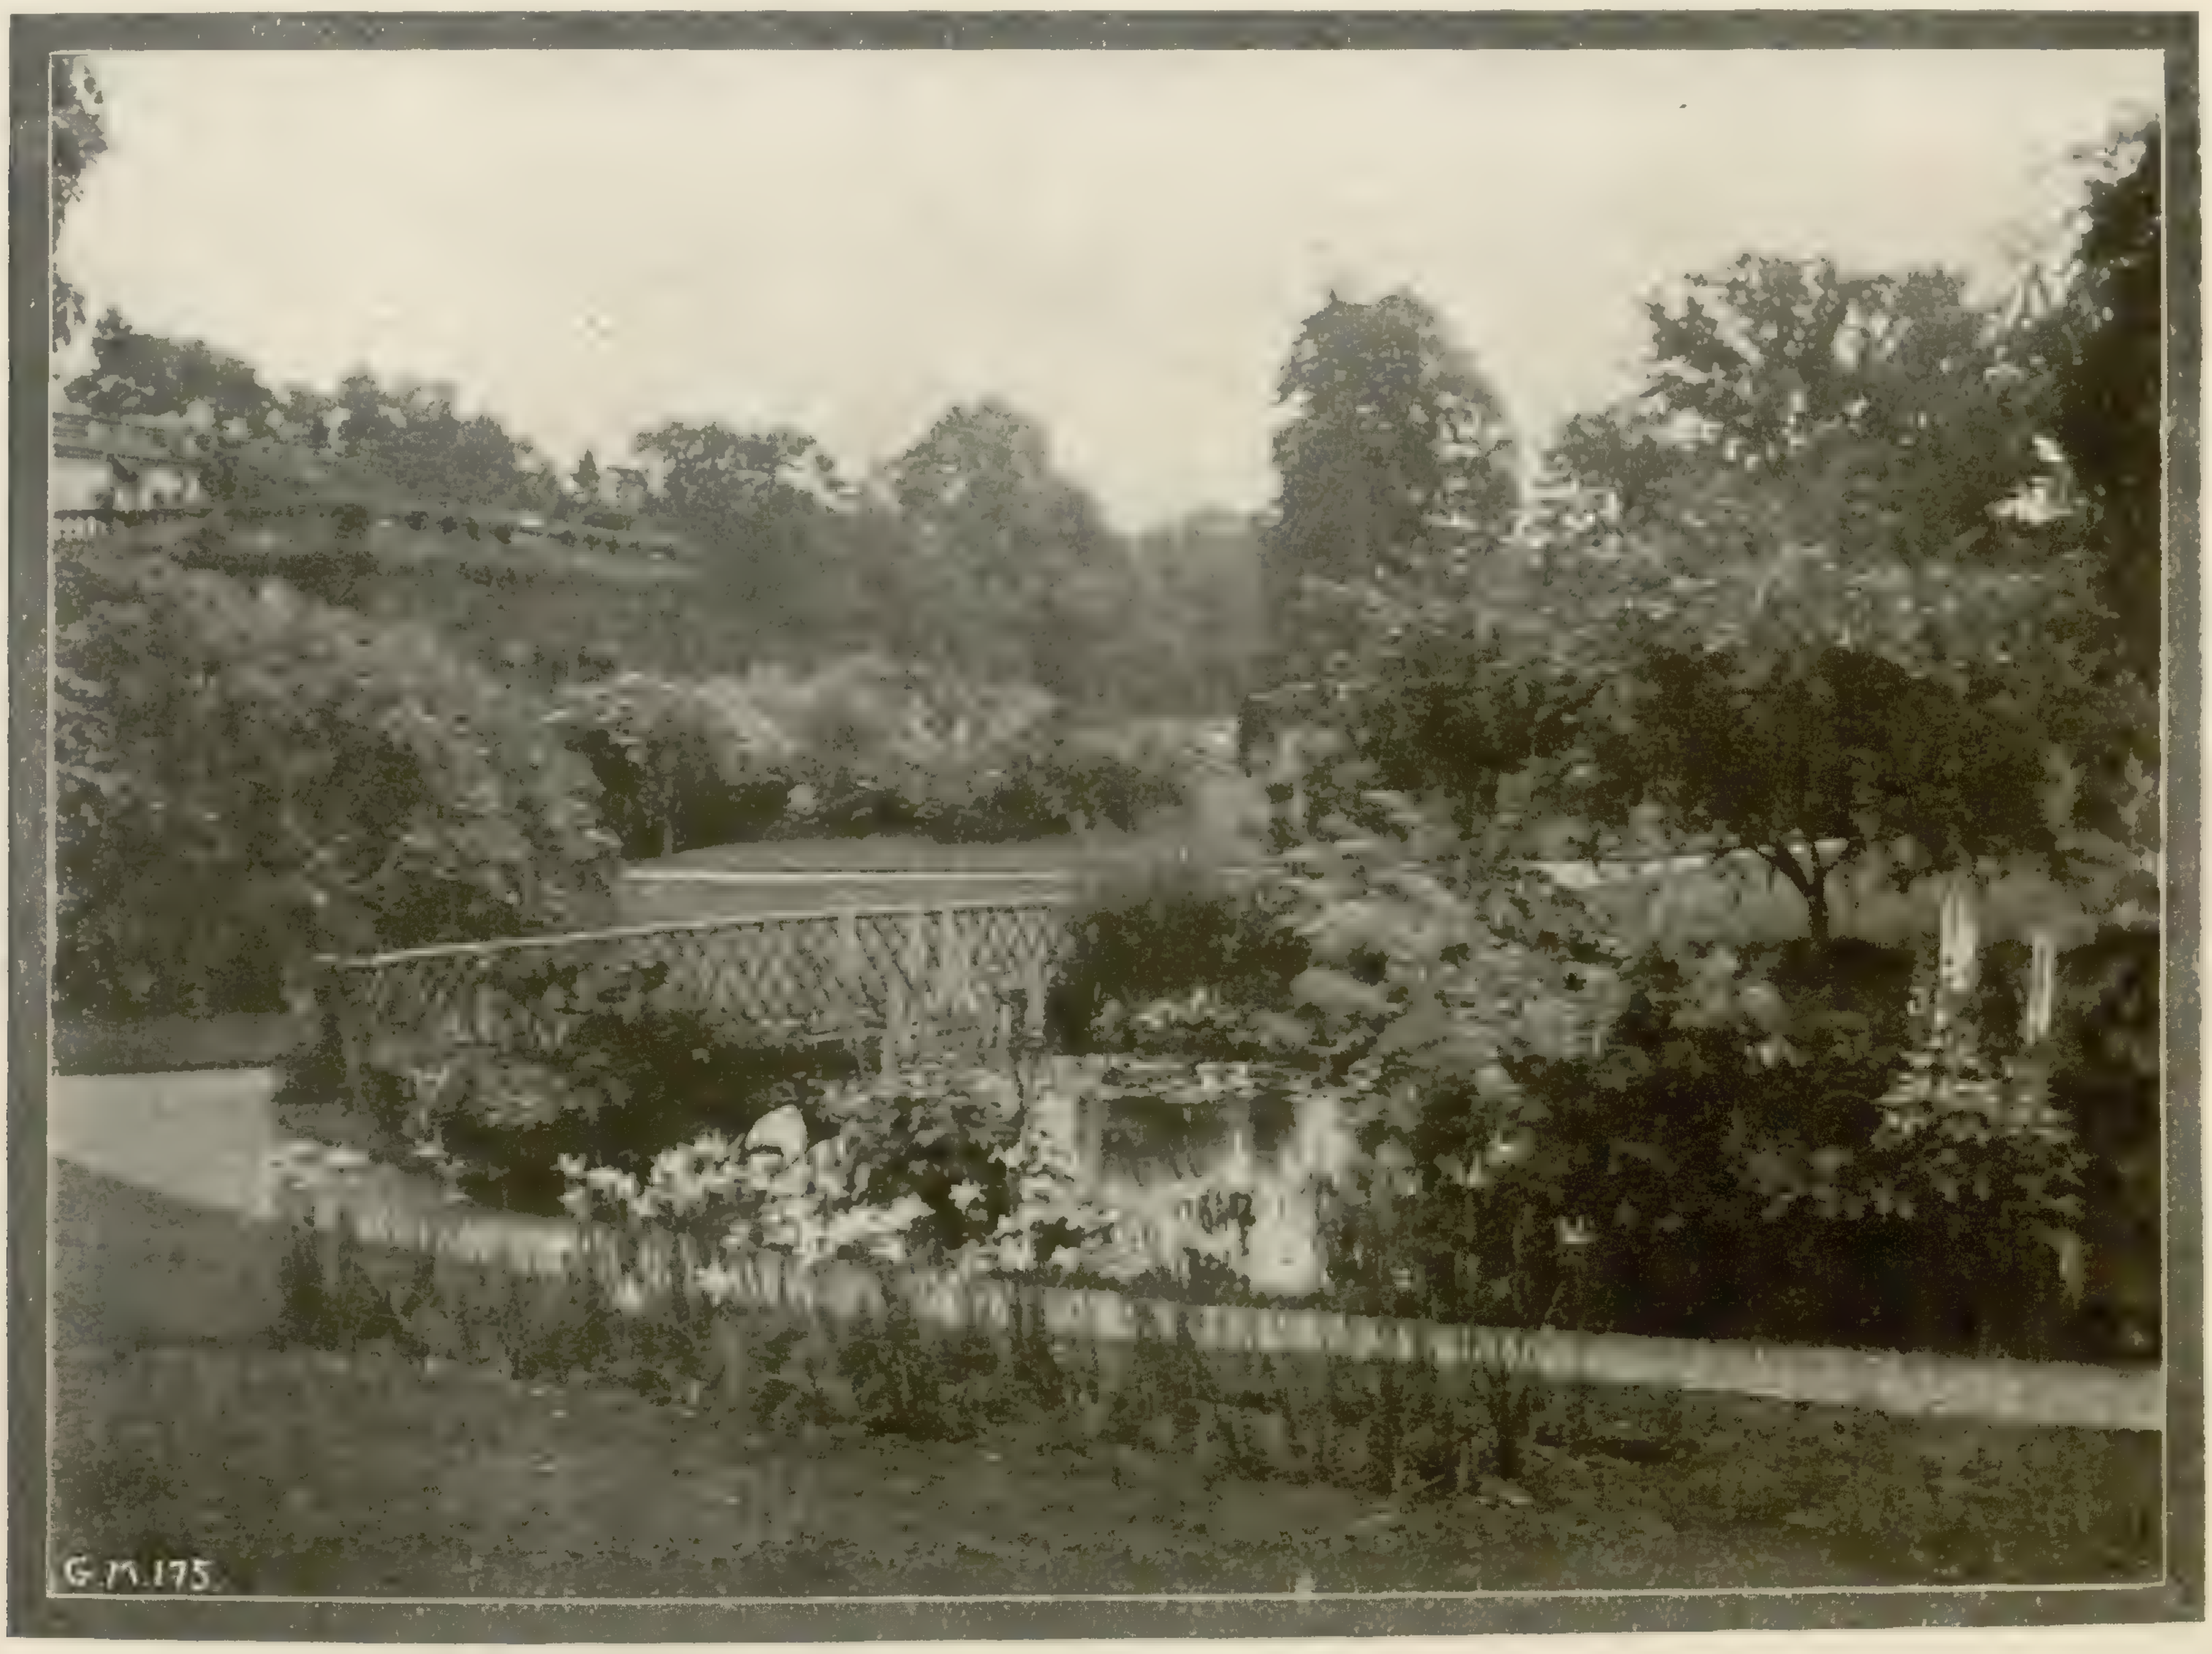
Considering the great beauty and utility of the laurustinus, especially in winter, I think it is somewhat strange that we see so little use made of it in gardens. Most large gardens contain their quota, though it is not such a big one as it should be, but the small garden often ignores it altogether. And yet, I question if a more generally useful shrub can be grown, taking one season with another.

Last autumn was, of course, an exceptional one in many ways, but it is worth recording that in my garden the laurustinus bloomed for several weeks before Christmas, and that on Christmas eve I cut a large armful of well-bloomed sprays. The subsequent snow and frost have bade it be quiet for a while, but the buds are not in the least injured, and a few hours of sunshine will again make the shrubs a sheet of white. As shown in the timely illustration and note on page 67, the laurustinus is entitled to rank high as a cut flower among the blooms which winter grudgingly allows us, for not only has it a pretty effect by any kind of light, but it lasts a surprisingly long time in good condition.

To see the flowers at their best, however, one must grow the plant in a cool greenhouse or conservatory. It makes an elegant pot specimen, and is among the best of all winter occupants for a quite cool house. Under glass the flowers open of a beautiful white, while in some plants they are so large that many people scarcely believe them to be laurustinus blossoms. I do not, however, hold with keeping the plants under glass all the year, as I have had much finer results by turning them out; if the pots are plunged to their rims in an outside border, watering need not give very much trouble in an ordinary season.

When planted in the outside garden, the laurustinus is often so huddled up among other shrubs that it has little chance of showing what it is really capable of. I have used it to crown a grass bank with the happiest results, to form a round bed in the centre of a lawn, and even to make a formal hedge. The latter was a great success, and I can confidently recommend the adoption of the idea to anyone who wants an uncommon hedge, and has a position or a garden not very much exposed to cold winds. Not that I think the laurustinus is as tender as many folk seem to imagine. I have seen it growing in some very wind-swept places near the sea, and the hedge mentioned above bore the brunt of south-west gales, notorious for their fierceness, with the loss of only an immature shoot or two. Soil of a heavy nature suits it admirably, but I have had the best results on the chalk.

E. J. KINGSHOME.



HOLBROOK PARK: A CHARMING GARDEN SCENE.

Names of Winners on Challenge Cups.—Those who have had the pleasure of holding, or even of beholding the challenge cups offered in competition by various horticultural societies, know full well that it is not the invariable custom to inscribe the tentative winner's name on the cups. Some cups, of course, do bear such records, and I think that all should do so. The fact that cups are so inscribed adds very greatly to their interest in the eyes of the spectator, while the holder must feel a glow of pride that his name should go down to posterity with those of other great ones. With a non-inscribed cup all records of the winners vanish, save so far as they are remembered by the record-makers or a few friends. May I commend this matter to horticultural secretaries?—E. J. K.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

PHAIUS.—P. grandifolius and its allies will now have their flower spikes in a forward condition. We grow practically all our phaius under comparatively cool intermediate house conditions. In fact, the winter-flowering cypripediums are cultivated in the same house, where the night temperature during winter is normally about 55 deg. I mention this because plants that have been grown under warmer treatment may possibly be in a more forward state, and thus my remarks may be considered out of place. We aim at having the bulk of this section and the Madagascar species P. simulans (better known in gardens as P. tuberculosus), with the hybrids derived from the influence of the last-mentioned, in flower about the month of March, and when they are well grown there are no orchids that give greater satisfaction. Here we use our specimen plants, often with upwards of a dozen spikes of flower on a plant, as ordinary subjects for decorative or furnishing purposes in the house. I have had some of our best plants from a month to six weeks in the house without their suffering the least injury. Indeed, it has appeared to us that taking the plants into the house while in flower has provided a natural rest that has proved more beneficial than otherwise. I am drawing particular attention to these orchids because I consider them a class that should be more generally grown in gardens. I know they are not favourites with orchid specialists generally, any more than are the deciduous section of calanthes; but, as we find the last-mentioned genus more successfully cultivated in general establishments where there are no special facilities or claims for orchid culture, we may also anticipate the same success in the cultivation of phaius. I find in gardens in this district that, where a few of the plants are grown, gardeners are in every way satisfied with the results, and grow them among the occupants of an ordinary stove.

PRESENT TREATMENT.—As the spikes advance, the plants should be placed in such a position that they may obtain full benefit from the available light. If placed at too great a distance from the glass the scapes are liable to become drawn and weakly, which must be avoided if possible, as the effect of the flowers being at too great a distance apart destroys the uniformity of the spike when fully expanded, and the texture and colour of the flowers are also poor. Give the plants every encouragement by supplying ample moisture, both at the roots and in the atmosphere, also until the flowers have expanded, and when the outside conditions permit. The best time to attempt any resting is immediately after the plants pass out of flower, but they must not at any time be permitted to suffer from want of root moisture. I hope to deal with potting requirements at a later season.

OTHER PHAIUS HYBRIDS, that is, those which have P. Humbloti as one parent, are even more easily grown than the above. Treated under the same conditions they are far more vigorous, and altogether superior in the quality of the flowers; they are also later in producing their flowers, and thus supply a useful succession. They are not nearly so plentifully distributed as the earlier hybrids, but I am sure that when their qualities are better known, they will become general favourites.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CAMELLIAS.—As a consequence of the rage for chrysanthemums, camellias have been ousted from many gardens, and in others they have been pushed into the background. This is to be regretted, for nothing can really take their place in the season at which they bloom. Not many years since a collection of camellias might be found in almost every garden of any pretensions, the central beds in many old-fashioned conservatories being devoted to them. To grow camellias well, care and regularity are necessary, as they soon fall a prey to scale and other insects if neglected. Healthy young plants can be purchased at a reasonable price, and these should be shifted into pots one size larger, draining them well, and using a compost of sound, rather strong fibrous loam, a sixth part of well-rotted manure, and rough sand or road grit. Firm potting is essential, and the plants should have the benefit of a comfortable temperature, and overhead syringing twice daily when sunny. Camellias enjoy a little shade, and do well beneath vines, provided the latter are planted some distance apart, and the trellis is not too densely covered with foliage.

MARGUERITES.—The main stock of these should be propagated during the autumn, but as the plants require stopping about this time the tops may be utilised, as these make the best of cuttings, and will be in time for bedding out; while those not required for that purpose make good plants for flowering in pots the following autumn and winter. Cuttings root freely in any cool pit, where they can be kept close, but I prefer to give a little bottom•heat from fermenting materials. A half spent hotbed will keep up enough moisture to prevent the cuttings flagging, and will also hasten root action.

PANICUM VARIEGATUM.—For the edging of stages or groups of fine foliaged plants, there is nothing more effective than this pretty grass. It is not of much value during the winter, except in the stove, but during the summer it may be used in the conservatory or in the greenhouse, and will do good service. Cuttings put in now will soon make useful mâterial; put about six cuttings in a 3in. pot in light, sandy soil, keep them close in the propagating frame, and in a few weeks they will be ready for potting into 5in. pots. With ordinary care they will keep in good condition throughout the season. Used alternately with Isolepis gracilis, they make a fine finish to any group.

PRIMULA VERTICILLATA.—This is a charming primula for the greenhouse in winter. It bears flowers of a beautiful yellow hue, borne in whorls or spikes 15 inches or more high. The delicate clear yellow of the flowers and the silvery tone of the foliage associates very pleasingly; the latter, more particularly underneath, is covered with a white mealy powder. This plant is preferably raised from seeds sown in February, in pans filled with finely-sifted sandy soil. Place them in a moderately warm house, cover with glass, and shade from the sun. When the seedlings are large enough to handle, transfer three of them into a 3in. or 4in. pot, according to their size. Allow them to remain in the same temperature until fairly well rooted. Then throughout the summer quite cool treatment should be afforded. All flowers that show during summer and autumn should be pinched off, thereby ensuring the production of vigorous flower scapes later. These pretty plants, when they are in full flower, are always much admired in the greenhouse during winter and early spring.—T. B. FIELD, Ashwellthorpe Gardens.

HARDY FRUITS.

PRUNING AND PLANTING.—As the season advances it will bring its own work, so that whatever pruning and planting remains to be done it should be pressed forward as fast as possible. If fruit culture is judiciously planned and carried out, I feel sure good results will follow, and it is quite possible that within a short space of time there will be higher prices for our English fruits, and a larger demand. When planting, it is as well to provide against the roots going down into a cold unhealthy subsoil by placing pieces of slate, tiles, or bricks below the roots, as this will help materially. In some soils little or no manure is required at the planting time, beyond a good mulching over and about the roots, but there are other soils in which manure is needed, otherwise the young trees become stunted and fail to make headway for years.

ORCHARDS.—When planting orchards do not omit to include some good late varieties. Bramey's Seeding, Newton Wonder, Dumelow's Seedling, Round Winter Nonsuch, Belle de Pontoise, and Northern Greening are all dependable. Earlier varieties are Lord Derby, Tower of Glamis, Warner's King, Stone's, Waltham Abbey Seedling, and Ecklinville. For dessert select Cox's Orange Pippin, King of the Pippins, Duke of Devonshire, Lady Sudeley, Scarlet Nonpareil, Worcester Pearmain, Cox's Pomona, Summer Golding, Adam's Pearmain, Ribston Pippin, etc.

ESPALIERS.—These need very careful attention with regard to pruning when in a young state, so as to form neatly-trained trees, after which the ordinary summer and winter pruning will suffice to keep the branches well studded with fruit buds. In the case of old trees, which may have been somewhat neglected, and the branches studded with long, useless snags, the latter should be gradually removed, cutting away more or less each year until the whole of the branches or tiers have been cleared. Young shoots and fruit buds will quickly form, and the trees will yield better and cleaner fruit. Apples and pears may be served in the same manner, and when in good bearing should be well supplied with manure, both in liquid and solid form.

GOOSEBERRIES.—If, owing to the destruction of the buds by birds, these have, so far, been left unpruned, the work should be taken in hand without further delay. Large bushes should be kept well thinned out, so that ample space is allowed for the admittance of air and light. In some instances a few of the old branches may be removed entirely, leaving clean, healthy last year's shoots to take their place. The aim should be to keep a neatly shaped bush, moderately thin, with plenty of young fruiting wood. Cut back to within a few buds of the base all inner shoots not required, and shorten the long shoots back, more or less, according to the length and strength of the growth. In most cases fifteen inches will be ample. After the pruning and thinning is finished, grub out any suckers which may have sprung up about the stems, remove a little of the top soil beneath the bushes, and then give the heads a thorough dusting with lime and soot; top-dress if needed, and mulch with good rotten manure. Birds are very destructive at times, so that repeated dustings of soot and lime will be necessary, and if strings of black cotton be fastened over and about the bushes it will help to keep the birds away. Last year's cuttings may be lifted and replanted, giving them more room to form neat bushes. Cuttings of gooseberries, red, white, and black currants, etc., should be made and put in firmly in rows twelve inches apart.

NEW TREES.—Before it is too late a careful inspection should be made of all kinds of garden trees, and fresh ones ordered to take the places of any which may have to be grubbed out in a few years. These should be trained neatly in the part of the garden most suitable for them. I always prepare young trees for the different purposes a few years previous, so that large spaces of wall, etc., may be filled at once, and fruit gathered sometimes the first year after planting. Peaches, nectarines, plums, pears, etc., all lend themselves readily to lifting, and in some cases the trees greatly benefit when lifted three or four years after having been planted.—H. MARKHAM, Wrotham Park Gardens.

THE FLOWER GARDEN.

EFFECTS OF THE RECENT SEVERE WEATHER are now becoming more and more apparent, many plants in bad positions being killed outright. Where such is the case, and a reserve supply of plants is on hand, filling in should be done as soon as possible. With us Myosotis dissitiflora and M. sylvatica, on our heavy cold soil, have suffered more than the wallflowers. Cistus crispus and Phlomis fruticosus have also been very badly crippled.

DIGGING.—Where spring bedding is not practised, all beds should now be well manured and deeply dug in readiness for summer bedding, every effort being made to keep well ahead with all work.

HERBACEOUS PLANTS. — Planting should be completed as soon as possible to enable the plants to flower well during the ensuing season. Lobelia cardinalis should be divided, and boxed or potted up, and remain under glass for some time longer in a quite cool, airy frame. Any remaining deciduous shrub and tree planting should also be finished, taking care not to allow the roots to be exposed a minute longer than necessary. Neatly cut over damaged roots with a sharp knife before being planted, and see that everything is securely staked or supported to prevent damage by winds.

CLIMBERS on pergolas and walls should also be planted during this month, care being taken that colours are properly blended, habits of plants suitable for their position, and soil suitable for each variety or kind of plant. The beautiful Tropæolum speciosum would give a very pleasing effect if planted more generally in a cool, but not water-logged or heavy clay soil; it does not mind strong sunshine on the top, and will in many cases, grow freely, producing a mass of its bright scarlet flowers during the season.

VIOLAS, ETC.—Rooted plants, in frames, of calceolarias, violas, antirrhinums, pentstemons, etc., should at once have their tops pinched out to induce bushy growth. Established clumps of violas, Dactylis glomerata, Festuca glauca, etc., may be divided and re-planted, and even if extra numbers are not required, it is better to divide and replant the youngest portion rather than allow them to become old and stubby, with bare centres.

SWEET PEAS.—A sowing of the ever-popular sweet peas should now be made. Sow a few seeds in pots under glass, and grow the plants quite sturdily until ready for planting out towards the end of March. Overcrowding should be avoided, though, as early flowers are always appreciated, thicker sowing for this than for succeeding batches may be practised; this applies more especially to those also now sown in permanent quarters outside, as their many enemies, ranging from pheasants and wood pigeons down to slugs, will probably take a heavy toll of them. A dozen good varieties are: Dorothy Eckford, Nora Unwin, White Spencer, David R Williamson, Duke of Westminster, Frank Dolby, Lady G. Hamilton, Coccinea, Evelyn Byatt, Gladys Unwin, King Edward VII., and Queen Alexandra.

DAHLIAS.—A batch of dahlia roots should now be placed in gentle heat for the production of cuttings; avoid a too high temperature, and when growths are about three or four inches long cut them off with heel attached or at a joint, and insert singly in small pots. Place in a close frame, or handlight in moderate heat. Also proceed with the propagation of lobelias, alyssums, ageratums, heliotropes, fuchsias, coleus, iresines, etc.

WALKS AND LAWNS.—See that all walks are kept well rolled, and lawns also well swept and rolled, and verges rolled and cut. When cutting with edging iron, guard against too thick a cut being made, as this speedily makes walks much wider than their allotted width, and spoils the effect. Merely straighten the verge edge. If any settlement or unevenness in lawns has occurred, the turf should be peeled and rolled back (or if the space is large, taken right off and laid aside), the top soil dug out, some rough soil placed in the bottom, and made firm, and the top soil and turf replaced, making all thoroughly firm and level. By returning the top soil to its original position a patchy appearance is avoided. When worn patches are made good, the new turf used should be as nearly as possible of the same kind of grass as the old turf.—E. F. HAZELTON, Knowsley Gardens, Prescot.

ROYAL HORTICULTURAL SOCIETY.

Annual Report.

The report of the council of the Royal Horticultural Society that will be presented to the Fellows on the occasion of the annual meeting, which will be held on Tuesday next, the 11th inst., has been issued. It need hardly be said that it is of an eminently satisfactory character; but we are pleased to have the additional proof which it affords of the splendid success achieved by the society during the past year. The report is of much interest throughout, but space will not admit of our doing more than give the following short extracts:

Research Station and Laboratory at Wisley.

The most important feature of the year's work, and one which, it is hoped, will be productive of far-reaching results, is the completion of the Laboratory and Scientific Research Station at Wisley. The opening ceremony was kindly performed by the Right Hon. Lord Avebury, P.C., F.R.S., on July 19, when several representatives of Government Departments, prominent men of science and horticulture, and members of the Surrey County Council, were present. The occasion was one of great gratification, for it brought the realisation of a long cherished, but long deferred desire for a scientific station under the direct control of the society, for research into the problems affecting plant life and plant disease at present confronting and baffling the gardener. Several very interesting speeches were delivered on the occasion which will be reported in the "Journal."

Among the first subjects to be investigated are soil-sterilisation by steam as a means of destroying those pests of plants which live in the soil; the influence of sterilisation on the plants subsequently cultivated in the soil; the bacteria of the soil; etherisation of plants; and certain definite plant diseases. Each of these subjects will entail a large amount of laboratory work, as well as of experiment in the garden.

Mr. Frederick Chittenden, from the Chelmsford Laboratories of the Essex C.C., and for some years secretary of our society's Scientific Committee, has been appointed director, having under his care both the research work and the students' laboratory, the latter at present accommodating 24 young men. The students training has thus been extended and improved, with a definite syllabus, and a time table apportioning their work between the gardens for practical work, and the laboratory for scientific study.

Prizes and Scholarships.

The council acknowledge with heartiest thanks the receipt of the £100 offered by Mr. Arthur W. Sutton, J.P., V.M.H., to inaugurate a prize scheme for the students at the gardens; and also the gift of an excellent photographic outfit for use at Wisley from Mrs. Hornby Lewis.

With reference to the prize scheme, which has not yet been definitely formulated, it is hoped that further donations will be forthcoming sufficient to secure an annual income of £15 to £20, so that the books or apparatus, given as prizes, may be worth working for, and serve as a real stimulus to the young men. The council would also welcome the foundation of scholarships.

Wisley Gardens.

The new garden is gradually being brought into thorough working order. Much, however, still remains to be done. Various trials of flowers and vegetables have been carried out, and Mr. George Massee, V.M.H., has conducted some original research work.

The number of visitors to the gardens admitted by Fellows' tickets during the year 1907 amounted to 8,818, as compared with 8,147 in 1906. This is exclusive of horticultural parties which were admitted by special arrangement, and would increase the total to over 10,000. The number would, no doubt, have been even larger but for the very unsettled weather of the summer of 1907.

The work in connection with the office of superintendent has so greatly increased that it has been found necessary to appoint an assistant superintendent, and Mr. Arthur C. Smith has been selected for the post.

Union of Gardeners' Associations.

The Union of Mutual Improvement Societies is another development of the past year. The council hope, by thus drawing the many isolated, but exceedingly useful, Horticultural Mutual Improvement Societies into federation with our society, and with each other, to strengthen and encourage them, and generally to promote their welfare. It is intended under this scheme to gather from existing societies the most suitable rules and regulations and general constitution for the information of newly starting societies, to keep a list of lecturers willing to assist them, and to furnish them with printed lectures, when a lecturer cannot be secured, or unavoidably fails to fulfil his engagement. All affiliated societies are included in the union.

Masters' Memorial Fund.

The council wish to commend the "Masters' Memorial Fund" to the support of the Fellows of the society. In the latter part of the year a meeting was held to consider in what way the late Dr. Masters' memory, and his work for scientific horticulture, could be most suitably perpetuated, and it was at once felt by all that the most fitting memorial would be to establish foundation lectures on the application of science to horticulture, to be called "The Masters' Memorial Lectures," similar to existing foundation lectures in law, medicine, and other sciences. The council gladly accepted the suggestion, and a circular letter was sent out to the Fellows, in response to which about £320 has thus far been received. It is greatly hoped that further donations may yet be made to the fund, in order that three lectures at least may be adequately endowed and so carry on Dr. Masters' memory to succeeding generations of gardeners.

Annual Progress.

The following figures will show the society's progress in regard to numerical strength during the past year: Loss by death in 1907, number 156, £216 6s.; loss by resignation, etc., number 520; income, £654 3s.; total loss number 676; income, £870 9s. Fellows elected in 1907, 1,209; income, £1,774 10s.; deduct loss, £870 9s. Net increase in income, £904 1s.; new Fellows, etc., 1,209; deduct resignations and deaths, 676; numerical increase, 533; total on December 31, 1907, 10,000. The council are pleased to record that the total number of Fellows, honorary or corresponding members, associates and affiliated societies is now 10,000, which is believed to be the highest number belonging to any British Royal Society.

The Temple Show.

By the renewed kindness of the treasurer and Benchers, the society held its great show for the twentieth year in succession on May 28, 29, and 30, in the gardens of the Inner Temple. The attendance was again a record one. In 1908 a similar show has been arranged for May 26, 27, and 28, when there will be a private view open to Fellows' tickets only, on Wednesday, May 27, between the hours of seven a.m. and noon. Fellows are particularly requested to notice that there will be no admission by payment to this private view; it will be reserved only for the annual tickets, transferable and non-transferable alike. This arrangement has been made to meet the wishes of many Fellows, and to obviate as far as possible the unpleasantness of overcrowding.

Deputations.

The council have with much pleasure received and accepted invitations to send deputations to the Cornwall Spring Flower Society on April 7, 1908; to the Jubilee meeting of the Yorkshire Floral Society on June 16, 1908; and to the Durham, Northumberland, and Newcastle-upon-Tyne Society's show on July 1, 1908.

Reduced Railway Fares.

At the request of a large number of Fellows, the council prepared a petition to the railway companies of Great Britain, asking for similar privileges of reduced railway fares to those granted to some other societies. The petition was signed by nearly 3,000 Fellows, and met with a courteous but decided refusal.

Committees.

The hearty thanks of the society are again due to the members of the committees, the judges, the lecturers, the writers of papers communicated to the Journal, the compilers of abstracts, and last, but by no means least, to the several examiners, and to others who, by their self-denying work in the society's service have largely contributed to the success of the past twelve months, and to the high position held by the Royal Horticultural Society among the practical and scientific societies of the world.

BRASSICA CROSSES.

The following are the results obtained by Mr. A. W. Sutton in his experiments in the crossing of brassicas under scientifically controlled conditions:

Types experimented with: Rape (Brassica Napus), Ragged Jack kale, and Asparagus kale—these appear to be closely allied to the Rape (? Brassica Napus); kohl rabi, Thousand-headed kale, and Drumhead cabbage (Brassica oleracea); swede, round, white-fleshed, swede, round, yellow-fleshed, and Swede Tankard, yellow-fleshed (Brassica campestris); turnips, yellow-fleshed and turnips, white-fleshed (Brassica rapa).

Crosses which failed to produce seed: Kohl rabi, Thousand-headed kale, Drumhead cabbage, x swedes, turnips, rapes, rape-like kales, and the reciprocal crosses; Ragged Jack kale and Asparagus kale x white turnips.

Crosses which produced seed, which, however, failed to germinate when sown in the open ground: White and yellow-fleshed turnips x white-fleshed swede; white-fleshed turnip x yellow-fleshed Tankard swede.

N.B.—Under artificial conditions some of these seeds germinated, but the resulting plants were sterile.

Crosses producing hybrid plants in F1, which hybrid plants, however, when put out for seed, were either sterile or were killed by the winter: Yellow-fleshed Tankard swede x Asparagus kale; Asparagus kale x white-fleshed turnip; yellow-fleshed Tankard swede x Ragged Jack kale; Ragged Jack kale x yellow-fleshed round swede; yellow-fleshed Tankard swede x rape; white-fleshed round swede x rape; rape x white-fleshed turnip; rape x yellow turnip; Ragged Jack kale x yellow turnip; white-fleshed swede x white turnip; yellow turnip x rape; yellow swede x yellow turnip; Ragged Jack kale x yellow turnip; white swede x yellow turnip; white turnip x yellow turnip; white swede x white turnip; yellow turnip x white turnip; yellow swede x white turnip.

Crosses which have been carried through F1, and have produced plants in F2: Thousand-headed kale x kohl rabi; kohl rabi x Thousand-headed kale; Drumhead cabbage x kohl rabi; kohl rabi x Drumhead cabbage; Drumhead cabbage x Thousand-headed kale; white swede x Ragged Jack kale; Ragged Jack kale x white swede; Asparagus kale x round yellow swede.

General note.—It will be seen that the cabbage types (Brassica oleracea) will freely intercross, but will not cross outside the B. oleracea class, while the rapes, rape-like kales, swedes, and turnips (Brassica Napus, B. campestris, and B. rapa) crossed with each other and produced hybrids, though many of these hybrids failed to produce seed in F2.

One of the most interesting scientific results obtained from the experiments has been that in nearly all of the cases in which plants have been produced in F2, these plants have reproduced the original forms or types used in the first crosses in definite proportions which agree with Mendelian ratios to a very large extent.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at ninepence per line, the minimum charge being Five Shillings. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

National Chrysanthemum Society.

This society held its annual meeting in Essex Hall, Essex Street, Strand, on Monday, February 3, at 7 p.m. In the unavoidable absence of Mr. C. E. Shea, Mr. T. Bevan was elected chairman of the meeting.

After the usual formalities had been disposed of, the report and balance-sheet, of which we give the leading features in an abbreviated form, were taken as read, and adopted.

During the year seventy-seven new members (twelve Fellows and sixty-five ordinary members) were added to the roll, as compared with sixty in the previous year. In February and March, 1907, some thousands of leaflets were distributed setting forth the objects of the society and the privileges and conditions of membership, and the best thanks of the society are due to those members of the trade who kindly gave valuable aid in the distribution of these circulars.

The strength of the society must not of course be measured entirely by the number of individual members on the roll. The list of affiliated societies is in itself a tower of strength, and in this matter the National Chrysanthemum Society occupies a unique position amongst societies which are devoted to the culture of one particular flower. On December 31 there were 110 suburban, provincial, and colonial societies on our register of affiliated societies.

Exhibitions were held in October, November, and December at the Crystal Palace as in former years. Your committee are pleased to report that the number of entries in the various classes showed an increase of about 33 1-3 per cent. over the previous year.

The shows for 1908, which will be held at the Crystal Palace, have been fixed for Wednesday and Thursday, October 7 and 8; Wednesday, Thursday, and Friday, November 4, 5, and 6; and Wednesday and Thursday, December 2 and 3.

Twenty-six meetings of the Executive Committee and sub-committees were held in 1907. Members were also in attendance at the society's shows at the Crystal Palace and Covent Garden, and the hon. foreign corresponding secretary also attended the French Society's shows in November at Paris and Orleans.

Seven meetings of the Floral Committee were held during the season, four at Essex Hall and three at the Crystal Palace. Mr. D. B. Crane presided over all the deliberations of the committee. The meetings of this committee are always of exceptional interest, and your committee would be pleased to see more of the members of the society availing themselves of the privilege of attending these meetings, when the various novelties introduced into the chrysanthemum world are to be seen in their earliest days.

During the season 215 entries were recorded and the following awards were made, viz.: Thirty-two first-class certificates and eleven commendations, whilst in several cases the exhibitors were asked to submit the blooms to the consideration of the committee on a future occasion. Silver medals were also awarded to Mr. W. J. Godfrey, Exmouth, and Mr. H. W. Thorp, Worthing, for interesting collections of new varieties submitted at the meeting held on October 28.

As foreshadowed in the last report, the society's Year Book was issued early in 1907 and was well received by the members. The best thanks of the society have already been tendered to the honorary editors, Mr. C. Harman Payne, F.R.H.S., and Mr. Charles H. Curtis, F.R.H.S., and also to each of the contributors. This publication assisted materially in keeping the society under the notice of the public, but from a financial point of view it must be admitted that the results were disappointing. All members received free copies, but the sales to the general public were very small and the income from advertisements was not as large as had been hoped. For this reason your committee decided with regret that it was inadvisable to incur this expense again in 1908.

The ordinary income of the society showed an increase over the previous year, but, having regard to the special expenditure, the committee deemed it advisable to transfer £70 from deposit account to general account. They have, however, resolved to re-transfer not less than £25 to deposit account from the current year's income and to continue the same policy until that account is restored to at least its original figure. The prize money in respect of all the shows has been paid.

Your committee received with the deepest regret the announcement of the President that, in consequence of continued ill-health, he would be unable to continue to fill that office after the close of 1907. Mr. Shea has been president of the society for the past five years, and your committee wish to place on record their sense of indebtedness to him for the many valuable services he has rendered to our society. Under these circumstances your committee have much pleasure in announcing that Sir Albert Rollit, D.C.L., LL.D., has consented to be nominated for the office of president during the coming year, and his name will be submitted to the members at the annual meeting.

In connection with the report, Mr. Simpson asked what was the loss on the Year Book issued in 1907. The Treasurer replied that the net cost of the Year Book was about £50.

After thanks had been accorded the various officers, Sir Albert K. Rollit was unanimously elected president for the ensuing year; Mr. John Green was re-elected as treasurer; Mr. T. Bevan as chairman; Mr. E. F. Hawes as vice-chairman; Mr. C. Harman Payne as hon. foreign corresponding secretary; and Mr. R. Witty as secretary. Mr. Joseph Lake and Mr. R. F. Scammell were elected auditors for 1908.

Mr. Charles E. Shea, the retiring president, was accorded an especially sincere and hearty vote of thanks for his services to the society, and he was unanimously elected a vice-president.

The election of one-third of the committee followed. Nine of the retiring members were eligible by virtue of regular attendance, for re-election. Retirements, etc., rendered other seats vacant, so that it was necessary to elect fifteen members. Six new nominations were made, and for the first time within our recollection there was no need for a ballot. The newly-elected members are: Messrs. R. Ballantine, W. H. Cull, W. Newton, R. F. Felton, G. Springthorpe, and J. Emberson, and the re-elected members are Messrs. W. Cassidy, P. A. Cragg, D. B. Crane, C. H. Curtis, A. J. Foster, J. McKerchar, E. Prickett, A. W. Seabrook, and J. Tyler.

The next business was to consider, and, if approved, to adopt, the following resolution, viz.: "That in Rule 16 the words 'No member of any committee shall be eligible for nomination as a judge at any of the society's exhibitions' be deleted, and that the word 'Honorary' be inserted at the beginning of the rule."

The new rule would then read as follows: "Honorary judges at the various exhibitions shall be appointed by the Executive Committee. The votes shall be taken by means of voting papers." This alteration was moved by Mr. Ingamells and Mr. Hawes, and supported by Mr. Simpson and Mr. J. Green, the latter showing that financial reasons had a good deal to do with the subject. Mr. Bevan said that possibly the amateurs would judge the trade classes, and vice versa, as at the National Rose Society's exhibitions.

Mr. Newman, of the Eastbourne Society, referred to the work done among children by his society in the distribution of plants and the provision of prizes at the November shows. Other speakers stated that similar encouragement was given at a number of the local shows around London.

A vote of thanks to the chairman brought the proceedings to a close within the hour.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE, January 28.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Professors Percival and Boulger, Rev. W. Wilks, Messrs. W. Cuthbertson, H. T. Güssow, C. T. Druery, G. Massee, W. C. Worsdell, G. Gordon, E. M. Holmes, A. W. Sutton, J. Odell, A. Rolfe, J. T. Bennett-Poë, J. Douglas, F. J. Chittenden (hon. secretary), and numerous visitors.

INHERITANCE OF PIGMENT IN PISUM SATIVUM.—Mr. C. C. Hurst, F.L.S., communicated the following note from Mr. E. A. Bunyard, of Maidstone, on "The Inheritance of Pigment in Pisum sativum." "The green and yellow colours of the cotyledons of Pisum sativum were selected by Mendel as one pair of constant differentiating characters, and from their apparent alternative inheritance the theory of gametic purity was deduced to explain results obtained in this species. The lack of any definite examination of the two colours in question led me to make some chemical and photo-chemical experiments as below, the pigments of the cotyledons alone being considered. The green pigment is, of course, chlorophyll, and thin sections mounted in glycerine show the chloroplasts well, and give the well-known 'hypochlorin reaction' when treated under the cover glass with glacial acetic acid. An alcoholic extract also gives the well-known bands in the red when spectroscopically examined, and the painted bands in the blue and violet. The yellow colour is due to a pigment of the xanthophyll series, pigments which are always found in association with chlorophyll in the green parts of plants. The point, however, which is of importance is the gradual fading of the green (Sachs' 'Degradation of chlorophyll'), and the presence of the xanthophyll. The green chloroplasts, as the seeds attain maturity, gradually lose their green pigment, and when it has entirely vanished they are left in the cell as pale-yellow globules. The yellow xanthophyll has, however, been present from the beginning, and the disappearance of the chlorophyll green has merely rendered it visible. The simultaneous presence of the two colouring matters can be demonstrated in this way. When a number of green cotyledons are steeped in alcohol a green extract, as referred to above, is obtained, and this fluid retains its green colour only so long as it is kept from light. When it is exposed to daylight, or even gaslight, it rapidly loses the green colour and fades to a yellowish tint. Upon examining this spectroscopically it is found to have absorption bands in the blue and violet identical with that of an alcoholic extract made from yellow cotyledons. This fading of the green is seen in the autumnal colouring of leaves, and in an inverse order the slow development of cholophyll when etiolated plants are exposed to light. These facts, I venture to think, render it necessary to modify Mendel's original conception in this special case, as it is evident that the conception of a factor for green and one for yellow, and the alternative inheritance of each is hardly in harmony with the facts. As all cotyledons pass through the green stage, and certain only pass through to the yellow, I would suggest that the factor may be not a factor of 'quality,' but a factor which extends or limits development."

Commenting upon the foregoing, Mr. Hurst wrote: "The above note by Mr. E. A. Bunyard is a valuable contribution to our knowledge of the nature of Mendelian characters in peas. According to Mr. Bunyard's results, green peas contain invisible yellows at all stages of their development, while yellow peas contain green in the early stages only. A yellow pea may, therefore, be regarded as due to the presence of a factor which causes the green to fade at an early stage of development, while in the green pea this factor is absent. The Mendelian units concerned are, therefore, not simply yellow and green, as Mendel supposed, for all green peas contain the yellow element as well as the green, but would appear to be rather the presence and absence of a factor which causes the green to fade."

HYBRID BRASSICAS.—Mr. A. W. Sutton read a paper which he illustrated by means of lantern slides, upon "Hybrid Brassicas," giving details of a large number of interesting experiments which have led to important results, although no forms of commercial importance have been produced. It is particularly interesting to note that Brassica Napus (Rape) would not cross with B. oleracea (the cabbage, thousand-headed kale, etc.), nor would B. rapa (the turnip and swede); and of further interest is the fact that the kales Ragged Jack and asparagus kale would not cross with the cabbage group, but crossed with B. napus, thus indicating that they were nearly related to that species. In all the crosses made, where crossing could be accomplished, the seedlings proved to be, as a rule, somewhat like both parents, and were practically all alike. Reciprocal crosses, however, did not always give identical results, but a question put by Mr. Chittenden elicited the fact that the same individuals were not always used in making these reciprocal crosses, i.e., the seed parent in the one case was not always the pollen parent in the other. In the second generation, segregation occurred in every case where it was possible to obtain seedlings (many of the F. generation proved sterile), and plants approaching in appearance the original types were produced. Thus when Ragged Jack kale was crossed with swede in the first generation plants somewhat intermediate were produced; but when seed from these was sown, of the resulting 198 plants, 160 had bulbs, 38 had none, 142 had swede-like foliage, 38 had Ragged Jack-like foliage, and 18 were intermediate. In some cases the figures obtained indicated that the characters segregated in the simple Mendelian proportions of 3 to 1, or 9 to 7, but it seemed evident that in other cases the matter was more complicated. In some of the crosses it is interesting to note that the hybrids developed a purple colouration, though in the foliage this was not to be seen in either of the parents. In the discussion that followed, Professor Percival and Messrs. W. Cuthbertson, J. W. Odell, and C. T. Druery joined, and it was remarked that in no case, although the type of plant was regained in the second generation, did the progeny approach in excellence of development the original parents; and, as Mr. Odell remarked, it was singular that the only plants that promise anything of commercial value among all the crosses raised were the result of more or less promiscuous interbreeding.

DISEASED PLANTS, INSECTS, ETC. — Specimens of injured plants, etc., were received, and will be reported on at the next meeting.

Bristol Gardeners' Association.

The best attended meeting of the present session was held on Thursday, January 30, at St. John's Parish-room; Mr. J. C. House in the chair. "Begonia Gloire de Lorraine" was the subject for discussion, and it was very ably introduced by Mr. T. Parrott, representative of the Bath Society. In his opening remarks the lecturer briefly referred to the origin of this beautiful begonia, giving B. socotrana and B. Dregei as its parents. It was most useful, he said, for table decoration, especially if the white variety was used with the pink, the two blending together well under artificial light. The best mode of propagation, Mr. Parrott said, was from leaf cuttings, which were preferable to stem cuttings. They made the best plants because plants grown from leaves do not throw flowers during their growing period as do plants from ordinary cuttings. Well-matured leaves should be inserted in boxes of sand or cocoanut fibre in December and January, and given bottom heat of from 75 to 80 deg.; they must be kept close and only watered sparingly; on the appearance of growths pot them in 3 in. pots, and finally in 6 in. pots, using a compost of two parts cocoanut fibre, one of leaf-soil, and one of fibrous loam, adding sand and charcoal. The soil should not be made firm; keep the plants in a cool house in summer and flower them in a temperature of about 60 deg. This was the gist of the paper. A good discussion followed, after which a very hearty vote of thanks was accorded to Mr. Parrott. For three plants in flower Mr. Curtis was first, and Mr. Wakefield second. Mr. Curtis was again first for two orchids, and Mr. Spry second. A certificate went to Mr. Jennings for Cypripedium villosum aureum.

Croydon Gardeners' Association.

At the opening meeting for the current session Mr. R. Edwards, Beechy Leys Gardens, Sevenoaks, read a paper on "Apples and Pears." Mr. Edwards is a successful grower, as evidenced by his exhibit of seventy-two varieties, all of which were excellent, which he staged for the purpose of illustrating his paper. In introducing his subject he directed attention to the all-important question of choosing the site and soil. Oftentimes when making an orchard sufficient depth of soil is not found, especially where chalk forms the subsoil, and the first thing to do is to make the soil up by trenching and the addition of other good soil and manure. A depth of 18 to 24 inches of soil should always be prepared for the reception of the tree, and care should be taken also that fairly good drainage is provided, for if the ground is waterlogged many varieties will not succeed. Standard trees should also be planted at least 26 to 30 feet apart. Bush fruit or strawberries may occupy the space between the rows, thereby making most use of the ground at one's disposal. In most gardens pyramid trees are the most useful

CLAY & SON, Manure Manufacturers and Bone Crushers, STRATFORD, LONDON, E.

these carrying excellent crops, and are kept within bounds better than standards. Wall trees are also serviceable, especially with pears. Mistakes are often made in pruning, especially with some varieties, and he advised studying the peculiarities of the varieties to a very great extent before attempting to use the knife. The end of July and beginning of August is a good time for summer pruning. Mulching and the application of good liquid manure during the hot summer were also spoken of as essential. Mr. Edwards advised that when making a garden a plan of the area should be made and the trees duly marked on it as they are planted, then, with the aid of a register of each one growing, notes may be kept of the progress made by each individual tree, and should occasion demand the removal of a tree to another part of the garden, or another tree substituted, one has always this record on hand to refer to. Excepting for a few early sorts of apples he advised leaving the fruit on the trees as long as possible, which would insure the keeping qualities to a greater extent, and preventing the shrinking and shrivelling of the specimens when stored. The fruit room was fully dealt with, and in this structure it should be made to maintain a uniform temperature. Fortunately for him he is not troubled with insect and fungoid pests to any great extent, however those he had had trouble with were eradicated by remedies given. The treatment of pears is very similar to that of the apple.

The members joined in a brisk discussion, and terminated the meeting with a warm and hearty vote of thanks to Mr. Edwards.

Besides Mr. Edwards' exhibit there was a fine seedling amaryllis, staged by Mr. H. Peckham. Mr. M. E. Mills put up a vase of white chrysanthemums, Nellie, and a fine specimen of the Cypripedium insigne, and Dr. Jackson sent three dishes of pears. The exhibitors were accorded a vote of thanks.

Sandhurst Gardeners' Association.

The usual meeting was held in the Church Schools, Sandhurst, on Tuesday, January 21. Mr. J. Evans presided over a large attendance. The paper for the evening was on "Mulching, Topdressing, and Liquid Stimulants," by Mr. W. J. Townsend, of Sandhurst Lodge Gardens. This was a most exhaustive paper, and contained a large amount of sound information on the subject. The mulching of freshly-planted shrubs, the topdressing of roses and other plants, and the proper uses of liquid stimulants were fully dealt with. A good discussion took place, and a hearty vote of thanks was accorded Mr. Townsend for his paper.

Mr. Townsend staged freesias and lachenalias in pots, and forced seakale, asparagus, rhubarb, and potatoes.

Cardiff Gardeners' Association.

The fortnightly meeting of the above association was held at the Philharmonic Restaurant on Tuesday, the 21st inst., Mr. H. R. Farmer presiding. Mr. Powell, the representative of the Newport Gardeners' Mutual Association, delivered a very interesting lecture, which was greatly appreciated by the members on "Miscellaneous Grouping."

Mr. Graham opened the debate, which produced a very keen discussion. The heartiest thanks of the meeting were accorded Mr. Powell, who said it would give him great pleasure to give another lecture at a future date.

The Chairman referred to the loss the society would sustain in losing Mr. J. Graham, who is leaving the neighbourhood. Mr. Graham has been associated with the society for a number of years, and at one time was chairman. A very high tribute was paid him, and the sincerest wishes of the members for every success and prosperity in the future were tendered. For a lady's spray of violets the first, second, and third prizes were awarded to Messrs. Went, Malpass, and Wicker respectively.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

ERECTION OF SUN-DIAL.—Will "G. O., Harrow," please send name and address? We have destroyed previous letter.

WHITE TEA-SCENTED GARDEN ROSES.—D. R., Rugby: You will find White Maman Cochet and Souv. de S. A. Prince a pair of excellent white tea-scented roses for garden decoration.

FAILING ARAUCARIA.—M. B., Cromer: In a room heated and lighted by gas day after day during the winter few plants will live, let alone thrive. The gas fumes are the chief source of trouble, but drought at the roots and a very dry atmosphere are other causes of failure.

SLUGS AND CHRISTMAS ROSES.—S., Norwich: Place a ring of coal ashes round the plants, and dust soot over the ground within the ring. Sliced carrot, lettuce leaves, etc., may be used as traps, but they must be frequently examined for many successive days until the slugs within the ring of ashes are exterminated.

PELARGONIUM LEAVES.—A. G. M., Carisbrook: Some of the leaves suggest that the plants have been poisoned by the use of water or soil containing some deleterious matter. Others, the fresher ones, indicate damage by frost or very low temperature; perhaps the plants were too near the glass during the recent very cold weather. We do not understand your reference to Weed Killer.

MUTUAL IMPROVEMENT SOCIETIES. B. G. J., Towcester: You will find a complete list of Horticultural Mutual Improvement Societies and Gardeners' Associations in the "Gardening Year Book" for 1908 (1s. 2d. post free, from Messrs. W. H. and L. Collingridge, 148-149, Aldersgate Street, E.C.) With these are also included horticultural and botanical societies, and in every case the name and address of the secretary is given.

DEAN HOLE MEMORIAL MEDAL. —A. A. L., Winchester: We cannot tell whether you refer to the Dean Memorial Medal or the Dean Hole Memorial Medal. The former is a medal awarded by the London Dahlia Union at its autumn show; this year it will be for pompon dahlias. The Dean Hole Memorial Medal belongs to the National Rose Society, and is "awarded by vote at a meeting of the General Committee, or at the annual general meeting of the society, for some special purpose, as occasion might arise." So far as we are aware the Dean Hole Memorial Medal has not yet been awarded to anyone.

HORTICULTURAL CLUB.—G. S., Southend: The Horticultural Club is an association of amateur and professional horticulturists. It has rooms at the Hotel Windsor, Victoria Street, S.W., and holds a club dinner and conversazione on the first Tuesday of each month, when there is a R.H.S. meeting. The Horticultural Club and the Royal Horticultural Society are intimately associated, and always have been. The annual subscription to the club is one guinea. Candidates for membership must be proposed and seconded by members, and their names are posted in the club room from the time of proposal to the time of election or rejection. Mr. E. T. Cook (address as above), will forward all particulars if requested.

HERBACEOUS PLANTS.—R. S. H., Heslington: Wait until the end of March or beginning of April before moving and replanting your herbaceous plants. If the plants are to be put back in the same border careful arrangements should be made to thoroughly trench and manure the ground, and allow it to settle for a few days. Tread the ground firmly before planting. The plants lifted must be carefully looked after; if placed in a cold frame or shelter, and kept well watered, and shaded from bright sunshine they should take little harm, if their roots are covered with soil. Part them up just previous to planting. If you have the conveniences for so doing you might lift, part, and pot up a stock of the various subjects, keep them in cold frames, and proceed with the trenching at once. Large specimens should be placed in a frame, and sheltered from severe weather.

SWEET PEAS ON SAME SITE.—F. M., Epsom: A change of soil and site is good for all plants. In the case of sweet peas and other annuals, especially those raised under glass and planted out in early spring, the ground has ample opportunity to recover, and the cultivator has plenty of time to trench and manure the ground and ridge it up so that winter cold may sweeten it between the removal of one crop in autumn and planting the succeeding crop in spring. In a very real sense all leguminous plants fertilise the soil in which they grow, and they do this by means of the bacteria that find a home in their root nodules, and convert free atmospheric nitrogen to the uses of the plant. Never pull up pea and bean crops; always cut them down, and leave the nodules in the ground. If your ground has been well cultivated and sweetened you need not hesitate to grow sweet peas thereon again; we know a garden where for at least ten years sweet peas of splendid size and colour have been produced annually on the same plot of ground.

NAMES OF PLANTS.

L. C. W., Oxford.—Brassavola Digbyana.

H. S., Warminster: A variety of Cratægus Crus-galli.

B. F. K., Stanton. — 1, Cupressus macrocarpa; 2, Arbutus Unedo.

N. A., Keighley.—1, Cypripedium nitens; 2, Cattleya Percivaliana; 3, Asparagus verticillatus.

C. G., Rochester: 1, Colletia cruciata; 2, Hamamelis arborea; 3, Cypripedium insigne; 4, C. Harrisianum; 5, C. villosum.

F. H. S., Gerards Cross.—1, Nephrolepis exaltata; 2, Nephrodium molle corymbiferum; 3, Russellia juncea; 4, Centropogon Lucyanus.

FORTHCOMING ENGAGEMENTS.

TUESDAY, February 11. — Royal Horticultural Society, annual meeting, 3 p.m.; meeting of Floral, Fruit, and Orchid Committees, 12 noon; Scientific Committee, 4 p.m.

Horticultural Club annual meeting, 5 p.m.; annual dinner, 6 p.m.

WEDNESDAY, February 12.—Society of Arts meeting, 8 p.m.

FRIDAY, February 14.—Royal Gardeners' Orphan Fund, annual meeting and election, at "Simpson's," Strand, W.C., 3 p.m.

WEDNESDAY, February 19.—Society of Arts meeting, 8 p.m.

THURSDAY, February 20.—Linnean Society meeting, 8 p.m.

WEDNESDAY, February 26.—Society of Arts meeting, 8 p.m.

Index to Volume of the Gardeners' Magazine," 1907.—Those of our readers who have preserved the 52 numbers of the Gardeners' Magazine for 1907 with a view to having them bound for future reference, can obtain Handsome Cloth Binding Cases from the publishers, 148 and 149, Aldersgate Street, London, price 2s. post free. The index with title page is now ready—price 2d., or by post 2½d. The volume bound complete will also be ready in a few days, price 12s. 6d., by post, 13s. 4d.

Guides to Garden Work.—The publishers of the Gardeners' Magazine will be pleased to forward a catalogue of their gardening books, setting out full particulars of the contents of each work. The books, which are thoroughly practical, up-to-date, and well bound, will be of particular service to those interested in flowers, the greenhouse, or the garden. A copy of the catalogue will be sent post free to any reader who addresses a postcard to the Publishers, The Gardeners' Magazine, 148 and 149, Aldersgate Street, London.

PLANTS PROTECT, MONEY **WEST'S PATENT GARDEN SUNDRIES** SAVE, & LABOUR EASE.

Have been invented during 25 years of practical experience in horticultural sundries, that by the better cultivation of plants and the pleasure by which gardens are kept in order their expense is doubly repaid.

ORDER FORM. *(Address here.)*

(To be filled up and handed to your Seedsman to execute for free delivery, thus saving carriage.)

To Messrs. Kindly supply the following:

WEST'S PATENT GARDEN SUNDRIES.

Qunty. £ s. d.
,, **Raffiatape,** coils better than raffia. 1d. coil ties up 150 plants. 7 coils (100 yds.) for **6d.** ..
,, ,, reels, with holder to fasten in buttonhole, 250 yds., complete **1/6** each ... ...
,, **Wall Tree Fasteners,** aluminium. Fastens on and off any nail in a wall, 50 for **1/-** ...
,, **Powder and Spray Syringe,** most useful article, **6/-** each ... ...
,, **Nicofume.** Complete self-contained fumigator, holding ½oz. 95°/o nicotine, **6d.** ea., **5/9** doz.
,, **W.E.O.N. Insecticide.** Sold under a £20 guarantee. 6d. bottles **5/9** doz., **14/-** pint. ...
,, **Fumigator.** Copper cup, complete, **9d.** ... ...
,, **Hand Fumigator,** 2/9 each. ... ...
,, **Powder Diffuser, 6d.** each .. ..
,, **Tobacco Powder.** Specially prepared (introduced 1888), **6d.** per tin ... ...
,, **Westite.** The first and best slug and germ killer, **6d.** per box to **20/-** cwt. ... ...
,, **Beetle Killer Powder, 6d.** per tin ... ...
,, **Plant Pot Crocks.** For perfect potting, prevention of insects in o pot, etc., **2/9** per 100 ..
,, **Fertiliser.** Perfect plant food. Has stood the test for 20 years, **6d.** per box to **20/-** cwt
,, **Watering Can Spreaders.** Fits any watering can and gives a splendid spray, **3d.** each ...
,, **Weeder.** Saves weary weeding, for a lady can uproot hundreds of weeds per hour, **2/6** ea.
,, **Lawn Sand.** Has stood the test for 25 years, and now improved, **6d.** per tin to **20/-** cwt...
,, **Weed Killer.** Best and cheapest for killing weeds on walks, etc. Introduced 1888. **1/6** tin
,, **Aluminium Labels.** When written on with lead pencil the wording is legible and indelible. Founded on the 25 years' experience with the West's Patent Label. **1/6, 2/- & 3/-** per 100
,, **Layering Pegs** and **Verbena Pins, 9d.** per 100 ... ...
,, **Greenhouse Shading.** Introduced in 1888 and still the best. Green and cream, **9d.** box
,, **Garden Cuffs.** Keeps the coat cuffs clean. No gardener should be without them, **6d.** pair
,, **Flower Holders.** For button holes and ladies' sprays. The flowers are gripped and held in watertight nickel tube, so that the lady's may be worn downwards { Gent's, **7½d.** Lady's **10d.**

CARNATIONS.

A Grand Collection of all Sections. Our New Illustrated Catalogue, with Cultural Instructions, post free.

Special Offer during March and April of one dozen rooted Cuttings of American Carnations, in 12 choice varieties, for 6s.

TWERTON HILL NURSERY, BATH.

New Tomato "VICTOR."

This Tomato, the result of several years careful crossing and selecting, is, we have no hesitation in saying, the most prolific variety yet sent out. The fruit, which is of medium size, rich colour and splendid flavour, is borne in trusses of from 12 to 25 at every joint, and the plants are remarkably short-jointed. The flesh is wonderfully solid, and the seeds are few in number. Per packet, **1/-**

Illustrated Catalogue, Free on application.

THE GARDENERS' MAGAZINE.

NOTES OF THE WEEK.

The Royal Horticultural Society.

As will have been gathered from the extracts that were given in our issue of the 7th inst., the report presented to the Fellows at the annual meeting on Tuesday last was of a most gratifying character. The Council were able to show that an immense amount of useful work had been accomplished during the past year, and that there had been a material increase in the number of Fellows and a considerable augmentation of income. As so well stated in one of the earlier paragraphs of the report, the most important feature of the year's work was the completion of the Laboratory and Scientific Research Station at Wisley. The opening of the station was an occasion for much gratification to those who are specially interested in the scientific side of the society's work. It not only brought the realisation of a long-cherished desire for a scientific station under the direct control of the society for the investigation of problems affecting plant life, but it immensely improved Wisley as an educational centre. Hitherto the training the society has been able to give the students in its gardens has fallen considerably short of the present-day requirements, owing to the impracticability of including practical scientific work in the curriculum. With the opening of the well-equipped Laboratory and Research Station, all difficulty in this matter has been removed, and the curriculum has been extended and improved by carefully proportioning the work of the students between practical work in the gardens and scientific study in the laboratory. Knowing how great was the ability displayed by Mr. F. Chittenden, the director, during his occupancy of an important position in the Chelmsford laboratories, we have no doubt that much scientific work of far-reaching importance will be accomplished at the Research Station. Not less gratifying is it to turn to that part of the report showing the losses and gains during the year. As we gave a summary of these in our last issue, there is no occasion to do more than express the gratification we feel, in common with others who appreciate the importance of a strong organisation, that the number of Fellows at the close of the year was 10,000, representing an income from subscriptions in round figures of £13,000. In this connection it is interesting to observe that there is a continuous increase in the accession of two guinea Fellows, 510 having been elected last year, as compared with 600 one-guinea Fellows, because it shows a greater appreciation of the value of the privileges of Fellowship by those able to pay the higher fee. As for several years previous the Temple Show gave a handsome profit, this last year being £1,062, plus a few shillings. On the other hand, the expenditure on the Holland House show exceeded the amount received for admissions by about £20, but this cannot be regarded as a loss seeing that the whole of the Fellows had free admission. While the two great summer exhibitions have been steadily increasing in public favour, the fruit show has been declining in popularity, and last year the amount received for admission was small as compared with the expenditure and the character of the display. The attendance of paying visitors was in deed such that, had the Council taken a narrow view of their responsibilities, the autumn show would probably have had no place in this year's programme; but they have not done so, and the exhibition remains in the schedule. It should be possible to infuse greater interest into, and also increase the educational value of the gathering by organising a conference on the first of the two days. On the second day there will be a meeting of delegates of gardeners' societies. The hall continues to increase in popularity, as evidenced by the fact that the net income from lettings amounted to £2,051 10s. 10d., a sum sufficient to pay ground rent, rates and taxes, gas and electric lighting, insurance, water, and depreciation, a result that is eminently satisfactory. On the year's work there is, after investing a considerable sum, a balance of £6,477 12s. 8d., and we allude to this for the purpose of mentioning that, with an income of £20,000, there is precisely the same care in the administration of the funds as when the income was £2,000, and in this respect, as in many others the Council have set an excellent example.

MR. T. H. COOK.
Head Gardener to His Majesty the King, at Sandringham.

Mr. T. H. Cook, whose portrait we have the pleasure of giving in this issue, is especially deserving of a place in our gallery of notable horticulturists and botanists, for he occupies one of the most important positions in the United Kingdom, and fills it in such manner as to prove to demonstration that he possesses administrative ability and cultural skill of an exceptionally high order. Some seven or eight years have elapsed since His Majesty the King appointed Mr. Cook his head gardener at Sandringham, and during this period he has fully justified the anticipations of those friends who were acquainted with the splendid work he had accomplished at Gosford, the fine seat of the Earl of Wemyss and March, during the seven or eight years he occupied the position of gardener there. The ability displayed by Mr. Cook during the period he had charge of the Gosford gardens was such that, although a quite young man, he became known as one of the foremost gardeners in Scotland. Even more remarkable have been the abilities that he has brought to bear upon the Royal Gardens at Sandringham during the period they have been under his charge, and as the result, the maintenance is such as to both delight and surprise those who have had opportunities for visiting them.

Foreign Fruits were imported in smaller quantities in January last than in the corresponding month for several years past, the decrease being more general than is usually the case. In the imports of apples there was again a considerable increase, the aggregate having been 336,212 cwt., of the value of £190,467, against 323,758 cwt., of the value of £187,541 in January, 1907. In the imports of apricots and peaches there was a very large increase, the total being 3,608 cwt., of the value of £9,776, as compared with 229 cwt., of the value of £1,803. Bananas dropped from 452,266 bunches in January, 1907, to 318,776 bunches last month, the values being £122,975 and £88,753 respectively. In the imports of grapes there was a decrease in quantity of 196 cwt., and an increase in value of £385, the total having been 1,622 cwt., of the value of £4,475. The decrease in the imports of lemons was 35,091 cwt., representing a drop in value of £11,179. In the case of oranges the decrease was 387,759 cwt., of the value of £155,900. Pears and plums, on the other hand, were received in larger quantities. The imports of the first-named fruits were 2,871 cwt., of the value of £4,111, against 1,323 cwt., of the value of £1,399, and of plums 362 cwt., of the value of £847, as compared with 6 cwt., of the value of £28. In the imports of unenumerated fruits there was a drop of 6,579 cwt., of the value £13,124, the total having been 1,536 cwt., of the value of £2,638. The total value of imported fruits, inclusive of nuts, during last month was £638,483 or a decrease of £198,862.

Royal Botanic Society.—The Council of the Royal Botanic Society state in their quarterly publication that from January 1 last the Royal Botanic Club ceased to exist as a separate organisation. In the place of the previous complicated arrangements the Council propose that the annual subscription should be raised to £3 3s. per annum; and that every Fellow of the society have all the privileges hitherto appertaining to the club. As under the new arrangement the council will have full control of the club rooms, they propose to utilise them for the purpose of botanical lectures, and of concerts. Professor Bottomley, King's College, will accordingly lecture on the following Thursday afternoons at four o'clock: March 5, "Various Marriage Customs of Plants"; March 19, "Soil Fertility and Bacteria." Mr. George Gordon, V.M.H., will lecture on Thursday, February 20, at four o'clock, his subject being "Gardens of Roses." These lectures will be illustrated by limelight views.

Prizes for Hyacinths.—As some years have elapsed since there has been in London a competition for prizes for hyacinths, it is a matter of considerable interest that the Royal Dutch Bulb Growers' Society at Haarlem have presented to the Royal Horticultural Society liberal prizes for these flowers. There are twelve prizes in all, and these are offered in six classes, three for amateurs and gentlemen's gardeners and three for nurserymen. The first group comprises classes for eighteen, twelve, and six, and the first prizes are £8 8s., £6 6s., and £4 4s., and in the second the classes are for twenty-four, eighteen, and twelve, with prizes of the same value as in those for private growers. The second prize in each class is exactly one-half the amount of the first prize. It is stipulated in the conditions that, each bulb must be in a separate pot, the size of which is optional; no exhibit may contain more than two specimens of one variety, and no exhibitor may compete in more than one class.

N.C.S. Year Book.—It is a cause for great regret that the National Chrysanthemum Society cannot, for financial reasons, issue a Year Book during 1908, but what is still more regrettable is that so many members have looked upon the issue of 1907 as a commercial undertaking. In discussing any question of profit or loss on the printing and publishing of such a book its value to the members is the first and chief consideration. A question raised at the annual meeting drew the information that the net cost of the Year Book for 1907 was £50. This was regarded as a £50 loss on the publication. In round figures, the society has 400 members and 100 affiliated societies, so that 500 copies of the Year Book were sent out as part of members' privileges. These, at the modest value of 1s. each, would be worth £25, so that the "loss" is at once reduced by one-half. Further, the peculiar position of the society when the Year Book was being prepared, retarded publication. Earlier publication would, possibly, have resulted in more advertisements and wider sales. However, we are glad to see the committee has strong hopes of continuing the publication. If the members' privileges of attending the exhibition were disregarded in the same way, then the shows of 1906-7, allowing £25 for the last December show, and including special prizes and donations, show receipts amounting to £487 18s., and an expenditure of £623 17s. 1d., not including anything for secretarial work and printing. On the face of it this shows a loss of £135 19s. 1d. on the exhibitions, or of £67 19s. 6½d. for 1907 alone!

Lord Avebury has been elected president of the Royal Microscopical Society, and at the March meeting will deliver an address on "Seeds, with special reference to British Plants."

London's Open Spaces.—At the monthly meeting of the Metropolitan Public Gardens Association, a letter was read from the London County Council regretting that they were unable to purchase St. Peter's Square, Hammersmith, as a public garden site, owing to the high price asked. Various applications from poor localities for assistance in organising window garden competitions were granted. Progress was reported regarding the association's work of tree pruning in Kensington thoroughfares, and tree planting operations in East Ham and Walthamstow roads, and in Southwark Cathedral Yard. As regards several purchase schemes in which the association is engaged, it was reported that £600 was still required for 3½ acres of the Grove Hall estate, Bow, towards which donations of £20 each were announced from Lord Tredegar and Sir John Brunner, M.P.; £1,800 for nine acres in Barking Road, East Ham; and over £2,000 for the 30 acres at Gipsy Road, Norwood; while, as regards a proposed addition of 12 acres to Ruskin Park, S.E., it was stated that the Bishop of Southwark had become the chairman of a local committee, and that £8,000 were needed from voluntary sources.

Darwin Celebration.—The Council of the Senate of the Cambridge University has in a recent report expressed an opinion to the effect that a Darwin Celebration should be held at Cambridge next year. In support of this opinion, the Council direct attention to the fact that Charles Darwin was born February 12, 1809, and that the "Origin of Species" was published November 24, 1859. It would thus be possible to celebrate the hundredth anniversary of Darwin's birth and the fiftieth anniversary of the publication of his important work next year. The week commencing June 20 is considered the most suitable for the celebration.

Sunderland Gardeners' Association held its annual dinner the other evening with the Rev. Dr. Randell in the chair, and the function proved very enjoyable to those present. Mr. T. W. Bolam, in responding to the principal toast, said the past year's work of the association as regarded papers, discussions, and exhibitions, had been highly successful. The discussions had been taken part in by men of considerable experience; and their exhibitions, particularly the exhibition of sweet peas in August, were such as to give much pleasure to visitors and satisfaction to the executive. The committee were arranging in their programme for the coming year not only an exhibition of sweet peas but also a chrysanthemum exhibition, both of which, now that they had been able to obtain more commodious quarters, would be on a somewhat extended scale.

R.H.S. Guild.—At a meeting of old Chiswick men and past and present Wisley men, held at the Royal Horticultural Hall on Tuesday last, Mr. C. H. Curtis presided. A decision to form a guild of those who have been or are being employed in the R.H.S. Gardens was unanimously arrived at. A draft set of rules will be sent to all eligible members whose addresses are known, and a sub-committee has been formed to consider suggestions so that the rules may be placed before a general meeting to be called for the evening of the second day of the Holland House Show. Mr. Wallis, R.H.S. Gardens, Wisley, Ripley, is the hon. secretary of the movement.

The Imports of Vegetables during January were somewhat above the average, owing chiefly to the largely increased quantities of potatoes that were received from abroad. Of these tubers the imports were 372,184 cwt., of the value of £68,052, or an increase in quantity of 285,408 cwt., and in value of £50,380. Tomatoes were also imported more largely, the total having been 73,409 cwt., of the value of £60,773, the increase in quantity being 17,387 cwt., and in value £11,706. Onions, on the other hand, were imported in smaller quantities, the imports aggregating 603,782 bushels, of the value of £67,499, these figures representing decreases of 82,179 cwt., and £8,704 respectively. In the value of unenumerated vegetables there was a decrease of £9,280, the total having been £22,526.

Potato Experiments have been carried out under the auspices of the Education Committee of the Surrey County Council for the purpose of determining the relative merits of sets obtained from different parts of the kingdom. Tubers were obtained from four sources, and were planted in rows of equal length. The yield was: Irish, 666lb.; Scotch, 571lb.; Lincolnshire, 193lb; Surrey, 156lb.

Sherwood Silver Cup, which was founded by Mr. N. N. Sherwood, V.M.H., will this year be offered for twenty-four bunches of roses, to be shown with their own foliage, in vases, by amateurs, at the Holland House Show, July 7 and 8.

International Botanical Congress.—At the International Botanical Congress, held in Vienna in 1905, it was decided to accept the invitation of the Belgian Government to hold the third conference at Brussels in 1910, and Messrs. T. Durand and L. Errera were appointed chairmen of the Organising Committee. Early in 1907, owing to the deaths of M. L. Errera and Comte de Kerchove, the Belgian Government suggested that the fourth congress, in 1915, should be held at Brussels, instead of the third. Subsequently it was decided to carry out the original arrangement, and a short time since a meeting was held in the Botanical Gardens, Brussels, to form a committee for making the necessary arrangements.

Derivation of Angiosperms through the Gymnosperms.—Botanists, more especially those who favour the view that the derivation of the angiosperms should be traced through the gymnosperms, will be much interested, says "Nature," in the theory with regard to the embryo sac advanced by Dr. O. Porsch, of Jena. The original and essential points in the argument lie in the interpretation of the antipodal cells as an archegonial complex, and in homoligising the polar nuclei with ventral canal cells. This postulates an archegonium consisting of an ovum and two neck cells, and a vestigial ventral canal cell nucleus at each end of the embryo sac. Dr. Porsch bases his arguments on a sequence starting from the condition of numerous archegonia found in Sequoia through types of the Cupressaceæ and Ephedra, where the archegonia are reduced in number and complexity, to a hypothetical case of two archegonia, at first juxtaposed, but subsequently located at the poles of the embryo sac.

Change of Seed in Potato Culture.—With a view to demonstrate the advantages to potato growers of a change of seed from Ireland, the Irish Department of Agriculture made arrangements in 1906 with several agricultural colleges to conduct a series of experiments in England, Scotland, and Wales, with Irish seed, as compared with English and Scottish seed. The results were so satisfactory as to induce the department to repeat the trials last year, when experiments were carried out in fifteen English counties and four Welsh counties. The potatoes used in the experiments were purchased for the department by Messrs. Sutton, through the ordinary sources of supply, the only stipulation made being that in every case the tubers had been grown for at least the two previous years on the same farm. This method of procuring the seed was adopted in order that the supplies should be typical of the produce of the respective countries. The results of the experiments showed that Irish seed is equal to Scottish, and much superior to English. The average yields at 32 English centres were 9 tons 10 cwt. 1 qr. per acre from Irish, and 9 tons 5 cwt. from Scottish seed of the British Queen, and 11 tons 0 cwt. 1 qr. from Irish, and 11 tons 5 cwt. 3 qr. from Scottish seed of Up-to-Date, while at five Welsh centres the positions were reversed, the Scottish being superior in the British Queen and the Irish in Up-to-Date. The differences are slight as between the Scottish and Irish seed, but it is again demonstrated that a frequent introduction of fresh seed from a colder climate is advisable on the part of the English grower.

MELONS IN PERFECTION.

Although not liked by everyone melons are a valuable addition to the dessert table from early in May to the end of October. The past year was not an ideal one for high-flavoured fruit, as melons need plenty of sun while swelling and ripening, and without this finely flavoured melons are an impossibility. It must not be inferred that no other agency is required to add flavour to the fruit, there are many details connected with growing melons which, if overlooked, will result in insipid fruits. An excess of water at the roots, especially of a stimulating nature, and insufficient fresh air just when the fruits are on the point of ripening must be rigidly avoided.

It is a waste of labour, and likewise fuel, to attempt to cultivate melons unless a night temperature can be maintained of 65 degrees from the time of sowing the seed, and the middle of February is quite soon enough for an early summer crop. Seeds may be sown till the end of May, when the night temperature may chiefly be maintained by husbanding the sun in the afternoon. Fill some 3in. pots with fibrous loam with just a dash of leaf-mould, pressing moderately firm, and place two seeds in a pot, these to be covered with half an inch of soil, and stand the pots on a hotbed if at command, but wherever placed the seed will soon germinate in a temperature of about 65 degrees, five degrees higher being nothing to their disadvantage. Providing the soil is fairly moist no water will be necessary until the seedlings are through the soil, and even then much care will be necessary in applying water or the young seedlings will collapse. The syringe will keep them moist enough for several days together. The grower must keep the plants as short jointed as possible from the first, standing them near the glass. Support with a neat stake betimes, after pulling out the weaker plant, and keep a watchful eye on the tender foliage, that neither thrip or red spider effect a lodgement. If either pest does, sponge very carefully with warm water.

While the plants are being prepared the structure must be thoroughly cleansed and the walls lime-washed.

Bottom heat is necessary for melons, and may be provided by hot-water pipes or a bed of fresh gathered leaves. In our case we have both, but I have seen good crops of melons grown with the soil resting on slate slabs, with hot-water pipes some eighteen inches below. It must now be determined whether the melons are to be grown in pots or planted out on a ridge or mound of soil. In the former case 12in. pots are the most suitable. These must rest on a firm base if plunged in the leaf bed, or the plants will be pulled up by the roots as the bed sinks with decay, in fact, a similar catastrophe may happen on the planted out system, therefore, a close watch is necessary where fermenting materials are used, and the vines loosened if necessary. A bed ten to twelve inches in depth and twelve to fifteen in width will be required. Good loam, inclined to be retentive rather than sandy or of a light texture, should be used, and to it should be added a little bonemeal and finely broken mortar rubble or old plaster. Make the bed very firm with a rammer.

Reverting to the young plants, it may be mentioned that they should be ready to shift into 5½in. pots, or be transferred direct to their permanent quarter within a month of sowing. I usually shift them, first seeing that they are moist at the roots, and keep the ball of roots a trifle higher than the surrounding soil, for if much of the stem is buried there is greater liability of canker. If they are grown as single cordons, which is the best method, 20 inches should be allowed between the plants, and the leader trained to a trellis within one foot of the glass roof, and not stopped until within six inches of its allotted space, which ought not to be less than a six feet run. Rub off the lower laterals as they appear, and pinch the points of the others one leaf beyond the female flower; these usually show at the first leaf. If they do not the point should be nipped out, when often a fruit will show on the sub-lateral. Syringe in the morning and early in the afternoon until the female flowers expand, when artificial fertilisation must be effected until a crop has been secured, selecting two to four of the most even fruits so that all may swell away together, these to be supported to the trellis with nets or thin pieces of square board, with a hole at each corner to take pieces of copper wire.

Melons grown in pots require liberal supplies of water, often twice a day during bright weather, but under the bed system two or three times a week will usually suffice, but the soil should be tested each day to be on the safe side. As regards stimulants, weak guano water or diluted drainings from stables or cow stalls at each alternate watering will assist to swell up the fruits. Surface roots may be covered with fresh loam or horse droppings, although it is seldom we do this here, and our crops are always satisfactory. To maintain a supply seed need to be sown every three weeks, and from the date of sowing to cutting the fruit twelve to fourteen weeks will usually elapse, so that the end of July is quite late enough for the final sowing. Seed may also be sown in the prepared pot or bed if ready for it, the results will amount to about the same.

Varieties are numerous, some preferring the green flesh while others pin their faith to the scarlet, so that it is best left to the cultivator, with the exception of stating that Sutton's Scarlet, Ringleader, High Cross Hybrid, and Gunton Orange are good early varieties.

Bicton, Devon. James Mayne.

Thunbergia laurifolia. — This plant appeals to all flower lovers when in bloom, but to those who have not a warm house the beauty of this stove climber is denied. The flowers are light blue, and borne in clusters all over the plant. Cuttings of half-ripened wood strike readily, and, if potted on in a mixture of sandy loam, when rooted, they will soon develop into good plants. Here we grow them in ten-inch pots, and the results are very satisfactory. Perhaps it might succeed even better planted out; possibly some one might tell us of its behaviour when so treated.—W. D. Pope, Wareham.

Breaking up Chalk.—It is curious what a deep-rooted prejudice the ordinary garden labourer has against breaking up the chalk subsoil in a garden. In my experience I have never met with a man of this class who would willingly break up chalk. The objection is not based upon the hardness of the task—though that may, perhaps, occasionally weigh—but upon the idea that once the chalk is loosened it will drain—or such, as an old Kentish labourer put it—all the moisture out of the top soil. Of course, the theory is ridiculous; more moisture is likely to be lost through evaporation from soil above unbroken chalk than is ever lost by drainage through broken ditto. Anyhow, I've had enough chalk broken up, and always with the happiest results.—E. J. K.

SPRING FLOWERING TREES AND SHRUBS.

A careful perusal of any good tree catalogue brings forcibly to our mind the advance made in recent years among trees and shrubs, and that with the facilities now offered to planters to acquire a knowledge of them they must before long be instrumental in producing improved results in gardens where at present box, yew, laurel, and privet usurp and impoverish the land. At best, these produce a dull and uninteresting effect, not only by depriving the garden of the means, but also the power to stimulate and sustain the interest of their owners. As windbreaks and hedges these coarse shrubs have a valuable and distinct use at all times, but indiscriminate mixing them with finer shrubs should always be avoided.

At no period can the garden be more effectively brightened by trees and shrubs than in the spring season, and as the work of planting is seasonable, I have penned the following notes upon some of those which flower during these months, and where liberally employed they produce marvellous effects in the garden and adjoining landscape. They are recommended for the beauty of their flowers, though several also produce handsome fruit, while many are resplendent in autumn with richly-coloured leaves.

They are all hardy, though wind-swept positions should be carefully avoided and shelter first secured by planting common trees suitable to that particular district. In some cases other kinds will naturally suggest themselves to those best acquainted with arborescent vegetation. As a rule, I have named those most distinct, and having particular merit, and the remarks on the height and habit must be taken as applying to the type and not to the richer coloured forms that have but recently been put in commerce, consequently only represented in gardens by small specimens.

Amelanchiers include two fine trees valuable in the garden for their flowers and autumn tints. They are generally grafted standard high upon some allied stock, though also sold as dwarf bushes. A. canadense is the oldest, but in beauty is closely followed by A. oligocarpa, which is the most vigorous of the two. Flowers white in bunches.

The barberries are a host in themselves, with very good qualities. Berberis concinna is a small deciduous shrub, densely spiny, while the undersides of the leaves are silvery white, the flowers are yellow, like small pendant balls, distinct. B. Darwini is a well-known evergreen species, the flowers are rich orange-yellow, and most effective in a mass. B. stenophylla is a hybrid barberry, with branches of a pendulous habit; the flowers are yellow, and borne so freely as to almost hide the shoots. B. japonica succeeds best in partial shade, the stems are erect and sparsely branched; flowers yellow, surrounded by a rosette of stout leathery leaves.

Cercis siliquastrum, commonly known as the Judas tree, has round leaves with unbroken margins, and are glaucous green; flowers rosy-purple, produced in great freedom upon the naked branches. It makes a handsome and distinct specimen up to twelve feet.

The flowering cherries produce some of the finest effects in spring and should be given prominent positions in shrubberies or as lawn specimens, the double varieties flower equally as free as the single forms, and remain in perfection much longer, so that preference should be given the former in planting. Cerasus avium multiplex is the double white form of the wild cherry. C. pseudo-cerasus is an immense favourite in Japan, and it shares with the peaches the distinction of being among the finest spring flowering trees. It can be had in several shades of colour, mostly of a pink or rose carmine hue. Watereri and James H. Veitch are the two best named forms, and have very large flowers. The Mexican Orange (Choisya ternata) has bright glossy evergreen leaves, and the flowers are white and produced freely. It succeeds best upon limestone soils, where it soon forms a large specimen, but requires the shelter of a wall in cold districts.

Cydonia japonica makes effective spots of colour in the garden during spring. The type produces bright scarlet flowers. Cardinalis has flowers of a bright rose cardinal colour. Maulei, with very rich scarlet flowers. Of the white varieties Maulei alba is the best. Cydonias are effective shrubs when growing against walls, and are useful in positions which receive the minimum of sunlight, such as north walls.

Forsythia suspensa is a charming subject, and should be grown upon a pole, and the flowering shoots pruned to a couple of buds when the flowers fade, so treated it is a veritable cascade of gold in spring. It associates well with the bright forms of ribes, though a good background of evergreens helps out the effect, as both plants flower in advance of the leaves.

Magnolias require great care in planting, as winds are their greatest enemy, the slightest friction damages the flowers, which are wax-like in substance. Magnolias grow freely in any good soil free from lime, and plenty of room should be allowed at planting for future development, as established specimens resent transplanting. Three inexpensive sorts which are of great beauty are M. conspicua, with large cup-shaped white flowers, M. Soulangeana somewhat similar with a ruddy purple colour suffusing the outer surface of the petals; both make large bushes, and M. stellata has smaller flowers, which clothe the naked branches like great white stars. Young plants bloom very freely.

Amygdalus persica magnifica fl.pl., is one of the best and earliest of flowering trees, the flowers are deep carmine-red and quite enwreath the branches in spring. As a standard or lawn specimen this fine double-flowered peach produces a unique effect in its season.

The plums include many good trees, the best known being Prunus Pissardi, the purple-leaved plum. The flowers are snow-white. P. spinosa fl.-pl. has pure white double flowers, and P. triloba fl.-pl. bears blossoms of a delicate pink colour.

P. malus floribunda and the fine dark-flowered form known as atrosanguinea make fine dwarf standard trees, and if kept to regular heads they can be accommodated in very small gardens. Of the fruiting crabs, the best and most distinct is the Dartmouth, which produces fruit like a small King pippin, but brilliantly coloured crimson-purple. It crops freely in a young state. John Downie and Montreal Beauty are pretty small fruiting sorts, resembling the Old Siberian. A distinct crab is P. Neidzwetzkana, the leaves and bark are coloured a deep purple, and, although I have not fruited it, yet I can recommend it on the best authority.

Ribes sanguinea is an old plant in gardens, and still worth growing, as it flowers freely upon a north wall in the poorest soil, the form sold as atrosanguinea is the best. Lovers of choice shrubs will appreciate speciosum with its deep crimson flowers and leaves resembling gooseberry foliage.

The spiræas are so numerous that it is difficult to limit one's choice. Arguta is the best, whether seen on banks, in the rock garden or in ordinary shrubberies it succeeds under every condition and yields its rich harvest of white flowers with no niggard hand. Confusa is a good second, and, although a more vigorous shrub, is never coarse. Prunifolia fl.-pl. completes the trio. It flowers best in moist soil open to the sun, and in such positions the autumn colouring of the leaves is very rich.

Staphylea colchica produces pure white sweetly-scented flowers. It makes a large bush 8 to 10 feet high, but is more often employed as a forcing shrub than as a subject for permanent planting.

Viburnum plicatum is a very fine guelder rose from Japan, the growth is moderate, and the habit of the plant compact, while the flowers are produced with great freedom. It is a shrub for extensive planting, not only for its flowers but for the autumn colour of the leaves.

Xanthoceras sorbifolia.—This beautiful Chinese shrub must have a sheltered corner, the flowers are white, with a soft crimson eye, and are produced in small spikes resembling the horse chestnut, the leaves resemble the mountain ash, but are much finer cut. Old specimens do not move well, so that careful planting is imperative in the first instance. It flowers freely in a young state, and should be planted in soil free from lime.

THOMAS SMITH.

Walmsgate Gardens, Louth, Lincs.

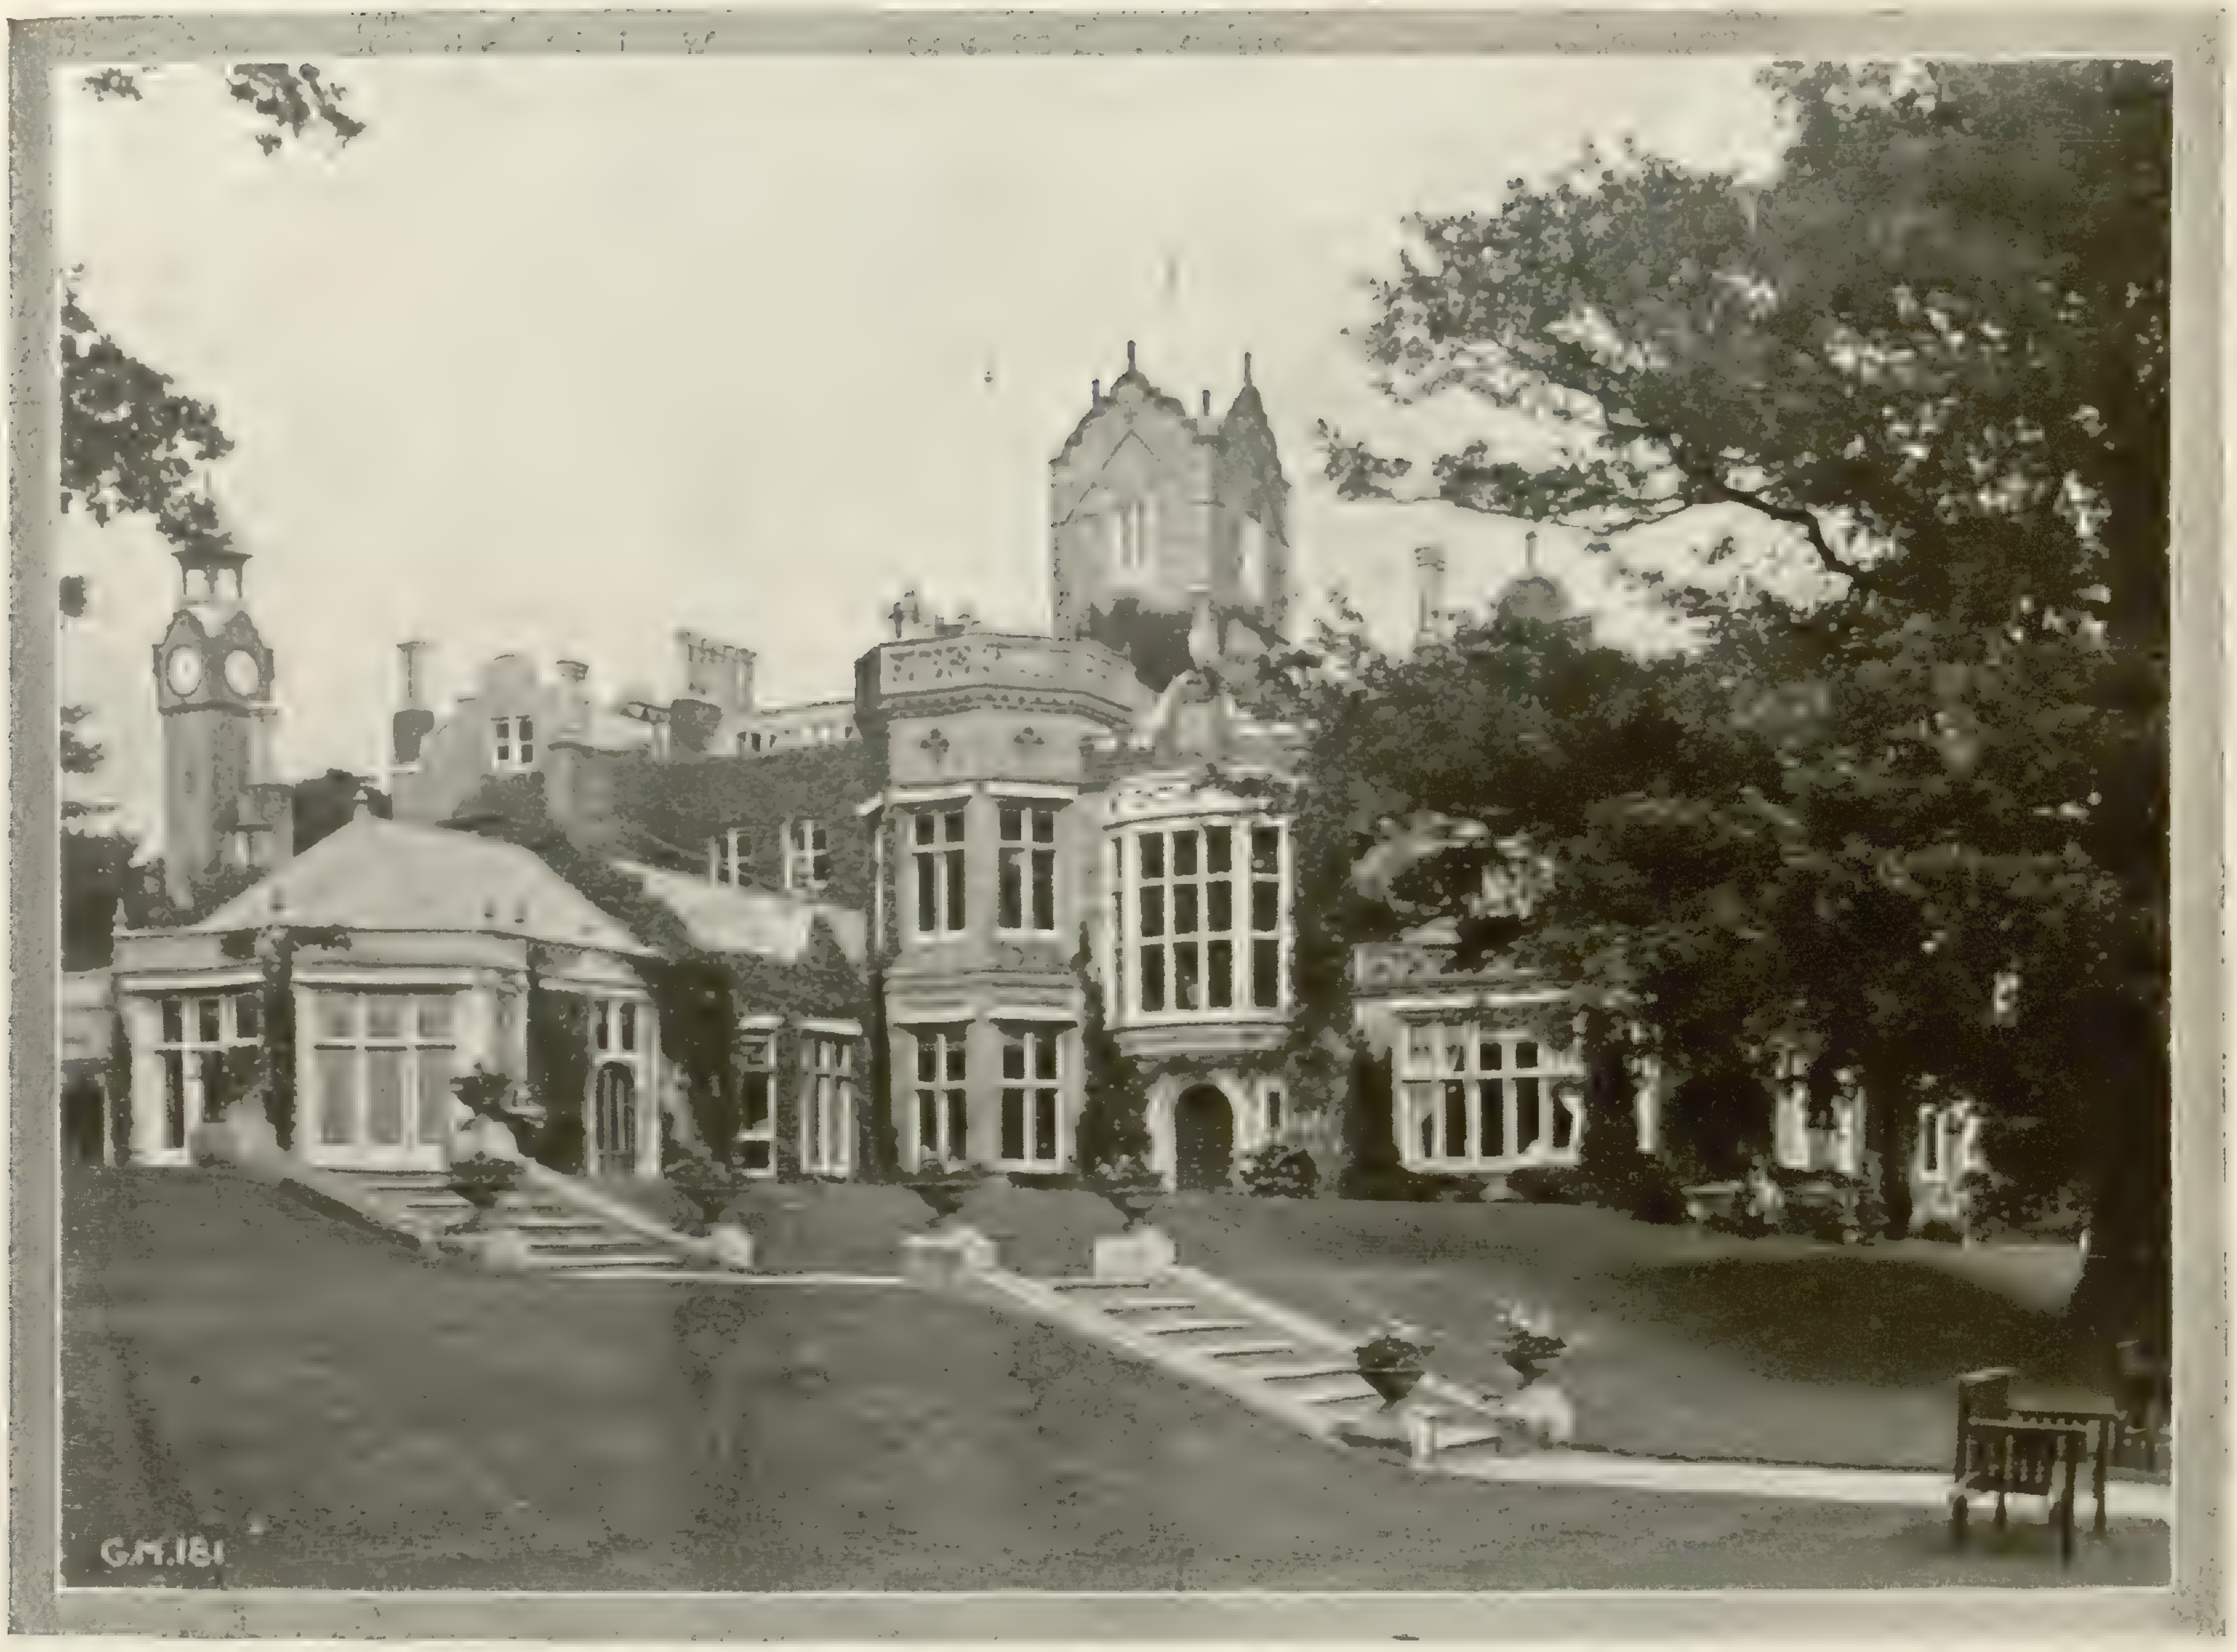
INULA ROYLEANA.

There have been several new additions to the inulas of late that bid fair to outrival the older I. grandiflora and I. glandulosa in size of flower, but not, I think, in general usefulness. I. Royleana, a sturdy Himalayan species, is particularly worth the attention of gardeners on account of the remarkable refinement and finish of its enormous flowers. I have tried for several seasons to grow it in a heavy loam overlying clay, but have been wholly unsuccessful. Last autumn I saw it in several gardens, the soils of which were all light and sandy, and in each case it presented a picture of rare beauty everyone could admire. It had broad and somewhat coarse leaves that recall some of the lesser mulleins, stout stems, generally a yard high, rarely branched, but often in clusters of six or eight, all well leaved, and each bearing a large deep yellow flower at least six inches in diameter; the large disc, packed with thousands of florets, looked and felt like velvet pile, whilst the narrow petals, literally in hundreds, formed a delightful fringe of pale orange.

Although quite disinclined to recommend it as a good garden plant for heavy soils—experience proving its unsuitableness for such—there is no doubt of its value in light soils. Rarely have I seen such an imposing plant, and at a time (August and September) when many border flowers had passed their best. Although recommendable for light soils, it is doubtful if it will thrive in poor ones, the leafage and strong stems bespeak ample plant food, and in the gardens where it thrives deep trenching and ample manuring of the borders is carried out every three years. Seedlings are best with which to start a colony; they flower in the third year.

G. B. MALLETT.

Everyone interested in a garden should obtain a copy of the ALPHABET OF GARDENING, by T. W. Sanders. Thoroughly practical information is given as to soils, manures, seed sowing, planting, potting, bedding, pruning, grafting, forcing, hybridising, etc., with explanatory diagrams. Price 1s. 6d. net, by post 1s. 9d.; cloth, 2s.; by post 2s. 3d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.



WARNHAM COURT: THE MANSION.

SOME HORSHAM GARDENS—II.

Warnham Court.

Between three and four miles to the north-west of Horsham is the picturesque village of Warnham, with which much that is of interest is associated. In their bright green setting the well-built houses form a charming picture as seen from the distance, and the admirably kept gardens with which they are surrounded can hardly fail to give much pleasure to those who are interested in horticulture when passing through the village. Near to the village are Warnham Court, the fine seat of C. J. Lucas, Esq., and Warnham Lodge, the residence of Sir Henry Harben, both of which have gardens of high repute.

The first-named of these two seats has long been famous for its magnificent park, with its stately oaks and fine herd of deer, and for its gardens, in which both ornamental and useful plants have been cultivated with exceptional skill, and the hybridisation of orchids carried out with much success. The stately Elizabethan mansion, of which an illustration is given, was built by Sir H. Pelly, and occupies a commanding position in the highest ground in the park. From the principal windows and from the terrace on which the mansion stands views of wide extent and surpassing loveliness are obtained. Not only are there beautiful views from the mansion, but this is so placed that it stands out boldly from amid the stately trees with which it is associated as to present a charming appearance when seen from some miles distant.

The pleasure grounds, as befits so stately an edifice, are of large extent and great beauty, and they also abound in interest. The walk shown in the illustration of the terrace wall, with its wreaths of clematis and examples of other climbing plants, extends westwards for many hundred yards, and connects the mansion with the principal departments of the gardens. For two or three hundred yards it runs alongside a tall wall, clothed with exceptionally fine specimens of the handsome evergreen Magnolia grandiflora. On the closely-shaven lawn in front of the wall are excellent examples of the art of topiary, and numerous flower beds that are usually filled with leaf plants quiet in colouring, lest, we presume, the colours of flowers should be too bright to harmonise with the several shades of green that predominate. In proceeding westward we pass a group of large beds filled with the finest of the rhododendrons, which here, as elsewhere in the district, grow vigorously and bloom profusely.

Continuing a westward course we meet also with an old orchard of apple trees, that instead of having been destroyed when a new orchard was probably provided elsewhere, was converted into a rambling rose garden. In carrying out the idea so happily conceived by Mr. Lucas, who takes a keen interest in his gardens, rambling roses in variety were planted at the foot of the apple trees, one variety to each, and their growths trained up the stems. Some amount of regulation was probably done during the earlier stages to ensure a proper distribution of rose growths among the branches of the trees, but beyond that the roses have been allowed to grow in their own way, and a charming way it is. The effect produced by these old apple trees bearing their precious burden may probably be better imagined than described, and were a description attempted one might be thought to be indulging in exaggeration. Therefore it may be better to suggest that those who have old apple trees past the production of good fruit should follow the example that has been set at Warnham Court, and clothe them with roses, and then ask themselves whether in speaking of their charms exaggeration would be possible. While all the roses presented a beautiful appearance, Thalia, Euphrosyne, and Carmine Pillar appealed most strongly for admiration. Mention must also be made of the fact that the charms of this old orchard are not limited to the season of roses; the grass under the trees is full off daffodils and other bulbs, and these provide a feast of flowers during the spring months. Still continuing westward we have evidence that hardy herbaceous plants are fully appreciated, and their cultivation well understood. This evidence is obtained from a spacious border, in which the finest of the hardy perennials have attained to a degree of development that is by no means common even in these days of hardy plant culture.

At the western extremity of the pleasure grounds a wild garden, extending over a large area, has recently been formed, and already this constitutes a delightful feature. When it has reached full development it will be one of the most remarkable gardens of the kind in the United Kingdom. For the purpose of this garden a field was selected with an irregular slope to the south, and containing clumps of trees, and within its boundaries have been formed big irregular beds of strong-growing roses, spiræas, heaths, honeysuckle, polygonums, and other subjects suitable to a garden formed in imitation of Nature's handiwork. Bulbs will largely contribute, in their several seasons, to the attractions of the garden, for in the winter of 1906-7 25,000 were planted. At the upper end a pavilion has been formed with old oaken timber, and the roof tiles have been covered with plants suitable for growing in such position, while others rise from between the flagstones forming the floor. From this pavilion, and looking over the garden, a charming view of the pastoral scenery hereabouts is obtained.

Returning in the direction of the mansion we pass through the spacious walled-in kitchen garden, which is intersected by a broad walk flanked on either side with borders of flowers. As shown in the accompanying illustration of this beautiful feature the borders are chiefly devoted to violas, and at the back are climbing roses, these latter being trained to a wire fence. Violas are cultivated with much success by Mr. Duncan, and it may be useful to mention that Countess of Hopetoun, Chancellor Walters, Mrs. Chichester, Kitty Hay, John Quarton, Devonshire Cream, Primrose Dame, Blut Tit, The Mearns, J. B. Riding, Goldfinch, and Duchess of Fife comprise some of the best in their respective lines of colour. The roses, it will be seen, bloom with great profusion, and especially conspicuous among them when the photograph of the border was taken were Allister Stella Gray, and Leuchtstern.

WARNHAM COURT: TERRACE WALL WITH CLEMATIS, ETC.

To the north of the mansion is a large pinetum containing a representative collection of coniferous trees. Here we find all the finest of the species and their golden and glaucous varieties in the most robust state of health. There is so large a number of beautiful forms, and their development so perfect that one cannot avoid a feeling of regret in finding it impossible to do more than thus briefly refer to them. Extensive, interesting, and beautiful also is the rock garden, and as it affords many object lessons of value, one would have liked to briefly sketch its principal features.

The glass department is of great importance; it occupies a considerable area, and much valuable work is annually accomplished within the structures. Mr. G. Duncan, the head gardener, is well known as a pastmaster in the art of fruit culture under glass; and of late years the gardens of Warnham Court have become notable for the hybrid orchids raised in them. Mr. Lucas is especially interested in orchids, and in the creation of new forms, with the result that several large houses once devoted to fruit production are now given over to them. The hybrid orchids that have been raised here and have obtained distinction would make a rather lengthy list, and it must therefore suffice to mention such fine forms as Lælio-cattleya Fascinator, L.-c. Lucasi, L.-c. Geoffrey, L.-c. Lawrie, L.c. Warnhamense, Brasso-cattleya Eric Lucas, Sophro-cattleya Warnhamense, Cattleya Iris Warnham Court variety, Cypripedium Edith Lucas, C. Warnhamensis, and C. Harlequin.

Warnham Lodge.

Not far from the centre of the village is Warnham Lodge, the residence of Sir Henry Harben, with its extensive, interesting, and admirably kept gardens, in which, as elsewhere in the district, are to be found object lessons of much value in their relation to modern methods of garden management. The mansion is of handsome elevation, occupies high ground, and from some parts of the gardens charming views are obtained of the surrounding country. Perhaps the finest of the prospects is that from the terrace which has been formed at the back of the kitchen garden. Here one has magnificent views of the ranges of hills that contribute so materially to the beauty of the scenery of the southern parts of Surrey. This terrace is a noteworthy feature of the gardens, and undoubtedly contributes in no small degree to the enjoyment they are so well able to afford. The ground slopes sharply at the back of the kitchen garden, and, taking advantage of this, a terrace some twenty feet wide was formed and supported by a wall with low balustrade. The wall at the back is clothed with ivy, and the whole appears so essentially part of the pleasure grounds that few visitors would imagine that the cultivation of fruits, flowers, and vegetables are being carried out on a large scale on the other side of the wall.

The pleasure grounds are extensive, and within their boundaries large numbers of the most beautiful of the deciduous and evergreen trees and shrubs have a place. Some are arranged in groups, and others singly, but, speaking generally, the shrubs are grouped in such manner as to produce a tasteful effect, while the trees are so disposed as to enable them to attain full development, and display their distinctive characteristics. Alongside that part of the carriage drive which intersects the pleasure grounds are many splendid examples of abies, cupressus, thuias, and other coniferous trees. The number of these is large, and not one came under notice that was otherwise than well furnished from the apex to the ground line, the distance between these points being in many instances represented by a goodly number of feet. Roses and ivy and other climbing plants are used with much taste in clothing the walls, as so well shown in the illustration herewith of the beautiful garden entrance.

Contiguous to the dressed grounds, and indeed forming part of them is a large area of finely-kept grass surrounded on two sides by a belt of firs and devoted in part to cricket and in part to choice trees. Sir H. Harben takes a keen interest in cricket, and the ground devoted to this summer game is so spacious and admirably kept that it is very properly regarded as the finest private ground in the Horsham district. The ground is made full use of, and is the scene each season of many splendid matches. The choice trees form an extensive arboretum, in which one might linger with pleasure and profit for a considerable period. Many notes were made, but for the present one can only say that one of the most noteworthy features is the group of three trees of Van Houtte's golden elm, which, as seen against the background of dark firs produces a rich effect, and demonstrates the value of this richly-coloured tree in the creation of garden scenery. The spacious rose garden, with its large circular beds of dwarf teas, hybrid perpetuals, and hybrid teas testify to the skill with which these fragrant flowers are cultivated, and, indeed, to the estimation in which they are held. Flowers of other kinds abound, for there is a long border in which hardy plants grow with amazing vigour, and there are groups of beds that are devoted to spring and summer flowers in their respective seasons, tuberous begonias of dwarf growth being used with surprisingly good effect in summer.

WARNHAM COURT: KITCHEN GARDEN WALK WITH BORDERS OF VIOLAS AND TRELLISES OF ROSES.

The kitchen garden is of special interest, for therein may be seen crops of the highest order of merit. There is no occasion to particularise where everything is so good, but it is not possible to refrain from making mention of the successful results obtained by Mr. Edwards in the production of late summer crops of peas. Strawberries are also grown with a success of which it is difficult to speak in measured terms. They are grown as annuals, and planted twelve inches apart in rows eighteen inches asunder. The crops of all the varieties were simply prodigious, and the fruits large and of high quality. On the fine walls and in the open fruit trees were in the best possible condition, as also were those under glass. The most noteworthy of the structures devoted to fruit culture was the span-roof orchard house, which has a length of ninety feet, a width of sixteen feet, and a height of twenty feet, and is splendidly furnished with peach and nectarine trees.

South Lodge.

Seldom are two such fine gardens as those of Leonardslee and South Lodge in close association, and still less frequent is it to find gardens that are, as it were, placed side by side so distinct in their several features. The road alone divides the two estates, and that of South Lodge must have been on the fringe of St. Leonard's Forest, if not actually within its ancient boundaries. South Lodge is the seat of F. D. Godman, Esq., and as will have been gathered from the foregoing observations is between four and five miles distant from Horsham, and reached by the same road as that described in connection with Leonardslee.

The mansion occupies a prominent position in an extensive park richly furnished with splendidly grown trees, such as oak, beech, and other kinds, and from the pleasure grounds that form its setting glorious views in the direction of the Sussex Downs are obtained. On the walls are many fine climbers; the plants that interested us most were the camellias, which grow here with great vigour, and produce in the spring their waxen flowers in great profusion. The features of the pleasure grounds, that extend almost as far as the eye can reach, are many, they are full of interest, and should be dealt with in far greater detail than is now possible.

The lover of hardy flowers who visits the gardens of South Lodge will find much to engage his attention in the magnificent border, of which an illustration is given herewith. It is no mere figure of speech to describe it as magnificent. The illustration indicates to some extent its magnitude and the high development to which the occupants have attained, but a few figures will help to make it more clear. Let it then be said that it has a length of 260 yards, not feet, and varies from ten to thirty feet wide. Commencing near the entrance gates, the border reaches the rock garden, around which it extends, and proceeds 140 yards beyond. Within this large area all the finest of the hardy perennials are represented, and it may be added at their best. Mr. Godman takes an active interest in hardy flowers, and Mr. Moody, who has charge of these fine gardens, is thoroughly conversant with all that relates to their selection and successful cultivation. Hence the splendid demonstration of the value of hardy plants that is found at South Lodge. Delphiniums, eremuri, phloxes, pæonies, monardas, achilleas, thalictrums, pentstemons, ostrowskias, and a host of other subjects abound, and, arranged as they are in bold groups, and attaining dimensions that are quite exceptional, the effect produced is such that lovers of hardy flowers visiting the gardens are not likely to forget.

The rock garden, as already intimated, is in close association with the herbaceous border, and is on a very large scale. There is no occasion to give figures for the purpose of showing its dimensions, as it will be seen from a glance at the illustration that the area occupied is a large one. Were it not that the vegetation with which the slopes are clothed far exceeds in diversity that which one meets with in mountainous districts, the visitor might without much difficulty give full play to his imagination and suppose for the moment that he was enjoying the charms of some specially favoured Alpine valley. With such large masses of choice subjects as those seen on all sides there is a strong temptation to enumerate them. The number is too large to admit of any considerable number having more than their names mentioned, and to do this would necessitate space being used with but little advantage to the reader. The handsome Carpenteria californica, as depicted in the illustration, grows to the size of a big bush, and blooms in great profusion. Skimmia japonica grows with a vigour that is quite exceptional, and annually bears a heavy crop of its brilliant scarlet berries. The rare Chinese orchid, Bletia hyacinthina, is found in a vigorous condition, and blooms abundantly every year, as does the little Chilian crocus, Tecophylæa cyano-crocus, producing annually hundreds of its intense blue flowers. Especially noteworthy is the rare Celmesia spectabilis, Crinodendron Hookeri, ramondias, blue and white, meconopses in variety, and the elegant Shortia glacifolia. The rock garden is particularly rich in primulas and androsaces, and of saxifragas there are about eighty species and varieties.

WARNHAM LODGE: ENTRANCE FROM GARDENS CHARMINGLY DECORATED WITH ROSES, ETC.

Beyond the rock garden is the extensive wild garden, in which the various ferns and flowering plants suitable for cultivation in a natural manner are arranged in bold masses and growing luxuriantly. To speak in detail of this charming feature is not now possible, but it must be said that the garden has been so judiciously planned and so skilfully managed that it constitutes a feature of much interest. The garden terminates in a small woodland lake, of which an illustration is given. Higher up in the garden the ostrich fern has been used with singularly good effect alongside one of the streams from which the lake derives its water.

The kitchen garden is of large extent, and, as one might expect from Mr. Moody's reputation, well planned and admirably managed. The fruit houses are numerous, and the occupants evince high-class cultural skill. Outside the walls of the kitchen garden are numerous plant houses with span roofs, of moderate dimensions, and so arranged as to admit of the various classes of plants that are in most request being grown by themselves. That the occupants were flourishing under the conditions that have been provided them was evident. Orchids form a strong feature of plant culture under glass, and contribute in no small degree to the high reputation the gardens so deservedly enjoy. Altogether seven houses are devoted to these fascinating plants, and it matters not what may be the season the visitor will be sure to find much that is of interest and an abundance of attractions. The collection is thoroughly representative, and the splendid condition of the plants throughout bear ample testimony to the skill of Mr. Giles, who has them under his charge. Many examples of exceptional merit might be mentioned, but space will not permit of further reference to this important department of the garden than to say that the cattleyas, cypripediums, dendrobiums, odontoglossums, and phalænopsis are of so high an order of merit that but few who are acquainted with orchids would venture to look for their superiors.

Wimblehurst.

A pleasant walk of a mile or so in a northern direction brings one to Wimblehurst, the charming residence of Mrs. Von Hartmann. Although less in size than some in the district, the gardens are of goodly dimensions, eminently attractive, and rich in interest. There are many notable features within these delightful gardens, but the one that will appeal the most strongly to the tree lover is that formed by the conifers tastefully disposed on the lawns, through which the carriage drive passes as it approaches the house. Here we find Douglas's fir, the Atlantic cedar, the Chinese juniper, and other conifers fifty feet or more in height, and absolutely perfect. Not less remarkable for their handsome appearance and perfect development are Pinus cenbra and Wellingtonia gigantea, and conspicuous by reason of its rich glaucous hue is the beautiful Picea pungens glauca. Deciduous trees specially adapted for garden ornamentation are plentiful, and by their growth suggest that the conditions which obtain are eminently favourable to them, especially conspicuous among them being the Camperdown elm, which sweeps the lawn with its flexile branches.

Roses are evidently great favourites of Mrs. Von Hartmann, for over the entrance to the mansion is a huge specimen of William Allan Richardson that annually produces a rich harvest of its attractively-coloured flowers, and in the pleasure grounds are roses in beds and trained over arches sufficiently numerous to annually produce a wealth of blossom. Another charming feature is the rockery, on which many of the choicest of the alpines make vigorous growth, and produce a profusion of their exquisitely beautiful flowers. Beyond the rockery is a pretty dell, in which various bulbs produce delightful colour schemes in the spring months, and the fine apple trees form a picture that could not well fail to appeal to even those who care but little about flowers.

Leaving the pleasure grounds with their manifold charms, we find in the kitchen garden ample evidence of skill in vegetable culture. We find also that Mr. Sparkes, the gardener, is an enthusiastic and successful cultivator of sweet peas, and that he is an accomplished fruit grower. In vineries and peach houses alike is there evidence at all seasons of health and vigour, and in the season of fruitage are abundant crops of grapes, peaches, and nectarines distinguished by high quality. In the open hardy fruits are admirably grown, especially interesting being the cordon pears, both on the walls and on trellises. In the conservatory a bright effect is produced by the zonal pelargoniums, which have been planted in the borders and allowed to rise to the staging.

In bringing these notes on the gardens in the Horsham district to a close, it remains for me to acknowledge, and I do so with much pleasure, the value of the assistance rendered me by Mr. Riley Scott, who is so well known as one of the trustees of the United Horticultural Provident and Benefit Society. Mr. Scott, who for a considerable period had charge of an important gardening establishment in Regent's Park, resigned that position some years ago, and purchased the Station Nursery at Horsham. Here his ability and energy displayed in the management of private gardens have stood him in good stead, and as the result the nursery has been greatly extended, the latest extension being the addition of six or eight acres about a year since.

George Gordon.

STOCKS FOR POT CULTURE.

The delicate perfume of these flowers, together with the length of time they remain in perfection, makes them particular favourites with most ladies. They are alike useful for cutting and for greenhouse decorations, and by making several sowings of the different kinds they may be had in bloom for the greater part of the year.

The first sowings should be made early in February, choosing such kinds as All the Year Round, Princess Alice, Monarch, Perfection, and Princess May. The seeds should be sown thinly in shallow boxes or pans, and afterwards placed on a shelf in the greenhouse, late vinery, or some similar place where they will germinate freely. When large enough to handle, or about an inch high, they should be pricked off into other boxes at a distance of about an inch apart, and when three or four rough leaves have been formed they should be transferred to four-inch pots, as when they have grown to any size they resent having their roots disturbed. If intended for growing on in pots they will need a shift into those of a size larger as soon as the soil in which they were first potted has become filled with roots, but if for planting out then they may be transferred to the open ground in April, as soon as all danger of severe frost is past.

When potted the plants should be stood in a cold frame to make their growth, but should have all the air possible in favourable weather. If well looked after these will give a wealth of bloom during the early summer months. A second sowing should be made in a cold frame in April. Plants from this sowing will bloom throughout the summer, and into the autumn if some of the intermediate varieties are chosen. They must, however, be potted up when small, and if the pots are plunged in the soil up to their rims this will keep them cool, and render unnecessary so much watering. As autumn approaches those not having flowered should have lights placed over them to ward off the heavy rains, as these spoil their blooms.

For winter flowering such kinds as Beauty of Nice, All the Year Round, Winter Pink, and the like are most useful. These should be sown in July or August, and kept growing without a check. Some prefer sowing the seed in the pots in which the plants are intended to flower, and when the seedlings appear thin to three in each pot, but we sow the seed in the open, then pot them up singly, for often when the plants are thinned the weakly ones are drawn and the strong ones left. These usually produce single flowers, whereas by potting them up this, in a measure, is avoided.

For spring flowering such kinds as East Lothians and Bromptons are most useful. The seed of these being sown at the latter end of July or early in August. As these plants will have to withstand the winter they should be grown as sturdy as possible through the autumn while the weather is favourable, that they may be the better able to resist the damp during the short dull days. When potted they should be placed in a cold frame having a southern aspect, that all the sun possible may act on their foliage. The lights should be put over them to ward off heavy rains, otherwise the soil would in all probability become saturated, but air must be freely admitted on all favourable occasions. In spring, when the plants begin to show signs of flowering, weak liquid manure should be given to induce them to throw up stronger spikes, for the longer these are the more useful will they be for cutting. No attempt should be made at forcing the plants into flower, but should they be required at any special date they may be introduced into an airy greenhouse or vinery, where the temperature ranges from 40 degrees to 45 degrees, as this will suit them admirably.

Wintered in a structure of this kind the flowers will be clean and fresh looking, and for decorative purposes most useful. Stocks thrive best in a good rich compost, and some of the kinds, when well grown, will produce spikes from a foot to eighteen inches in length. The white-flowered kinds are the most useful of all, as these come in for a variety of purposes, therefore it is well to grow a good batch of them.

H. C. Prinsep.

BUDDLEIA ASIATICA.

Visitors to the winter meetings of the Royal Horticultural Society will be well acquainted with the value of Buddleia asiatica for flowering at this season of the year, but there are doubtless many who have not yet had it brought under their notice. Although it is only within the last two or three years that this buddleia has been generally grown, it was in cultivation in this country over thirty years ago, and was figured in the "Botanical Magazine" in 1877. It would then appear to have been lost, until re-introduced by Mr. E. H. Wilson. when collecting in Western China. This buddleia belongs to the same group as most of the species that we have received from Western China of recent years, the best known of all being Buddleia variabilis. This last-named, however, is hardy, while B. asiatica is tender, and valuable only, at least in this country, for greenhouse decoration. On the Riviera it has, I believe, already become popular. Grown in pots it forms a freely-branched specimen of rather slender growth, clothed with lanceolate leaves, finely serrated. The white flowers are individually small, but densely arranged in long slender racemes, so that when in full bloom a specimen is exceedingly showy and graceful. Another desirable feature is the pleasing fragrance of the blossoms. Plants a yard high will flower well, or it may be grown double the size. Like most of its relatives, it can be readily increased from cuttings of the young growing shoots taken during the spring months. Potted in a mixture of loam, peat, or leaf-mould and sand, the young plants grow away quickly from the time they are rooted.

W. T.

SOUTH LODGE: BORDER WITH HERBACEOUS PLANTS.

CELERY.

Serviceable heads of this useful vegetable can be produced with comparative ease during eight months of the year. The beautiful specimens so often seen at exhibitions during August show what good cultivation can achieve in the production of supplies thus early.

Earliest Supplies.

To have finished and highly blanched heads in August an early beginning is necessary. A sowing of seed has to be made early in the year, and considerable care has to be exercised in pricking out and potting or boxing on the young plants, and preventing them from becoming weak during the dull days of February. This procedure in growing celery is only for producing heads for some special purpose, and is not generally adopted, for providing the main crop, which means, speaking generally, to carry over a supply from September to March.

SOUTH LODGE: VIEW IN ROCK GARDEN.

In the production of the main crop seed should be sown in March, and for the first lifting we find the old variety Sandringham White very good, with Wright's Grove pink and red varieties to follow, the latter being excellent for their keeping properties. The seed should be sown thinly in boxes or pans filled with a sandy, porous compost, and placed in a temperature of about 50 degrees. Germination of the seed is somewhat slow, and better results will be secured by placing a slate or sheet of brown paper over the boxes or pans to keep it in darkness till seen to be germinating. It should then be gradually exposed to the light. When able to bear full exposure place the young plants near the roof glass, plenty of light from the beginning being essential. It is important that they should develop slowly and sturdily, especially in their early stages. When the plants have attained to about an inch high, and are commencing to expand their leaves, they will be large enough. After being hardened off for a few days in a cool temperature they will be in a condition for

Pricking Out.

A light, shallow, cool frame, standing on a hard firm surface will be the best place for them. A bed six inches high should be formed in the frame, and this should consist of two-thirds finely chopped turf, one third of leaf-mould or spent mushroom manure, with a little sand mixed with it. They will soon commence to root freely, and grow vigorously. Put them six inches apart each way, and firmly fix each one in the soil as the work proceeds. Afterwards give a watering through a rose to settle the soil about them. Keep the atmosphere of the frame rather moist for a few days by giving but little ventilation. When it is seen that the plants have commenced root action in their new material gradually increase the ventilation. When they have become thoroughly established it will be beneficial to fully expose them during fine warm days, but a watchful eye will be necessary to avoid exposing them to biting cold winds or frosts, as exposure of either kind will impose an injurious check to growth.

Making and Preparing the Trenches.

There are several ways of preparing and arranging these. The single row trench, the double row trench, and the wider trench to carry three or more rows. After various experiments I find, taking all points into consideration, that the double row system is the most satisfactory with me for producing the ordinary culinary heads. It is economical in the matter of space, the celery can be easily watered, and the trenches are handier for moulding, and protecting purposes than the wider trenches. Moreover, the spaces between are utilised for growing various salad plants during the early part of the season. The trenches are more satisfactory when made early, whilst sufficient moisture is in the soil to give it a firm holding. About eighteen inches in width is considered sufficient for a free root run, and the soil stirred to about two feet deep. With some cold clayey subsoils considerable care is required in preparing the depth of the trenches to prevent the roots coming into contact with an objectionable stagnant subsoil. Where this is found it should be entirely removed, and fresh mould put in its place from the top. The celery plant luxuriates in, and indeed must have, a rich and liberal root run to give good results. Therefore, the best procurable farmyard manure should be used in forming the trenches, and thoroughly incorporated with the soil.

Planting Out.

About the beginning of June will find the plants in vigorous growth, with their roots running freely through the soil in the frames, and ready to be removed to their permanent quarters. In doing this it is essential that it should be carried out with the least damage or check to the plants. They must be thoroughly hardened off by full exposure for a week at least before planting out. Previous to removal give the roots a sufficient watering to well soak the bed of soil in which they are growing. It will then be possible to cut them out with a ball of soil adhering to the roots and convey them to the prepared trenches. They should be planted twelve inches apart, and if handled with care they will hardly feel having been transplanted. As the trenches are planted give another soaking of water. A dull day is preferable for planting, but not altogether necessary if carried out with proper method. Should the sun be hot a few boughs may be lightly laid over the trenches to break the strongest rays, and this will be all that is required. Attention will be needful with regard to water during the growing season. The amount to give will depend upon the rainfall of the season, but on no account should the soil be allowed to become unduly dry, as this, with other checks, is a fruitful cause of the plants running to seed. Be careful to keep the leaves during the summer and autumn dusted over with soot to prevent the celery fly laying its eggs upon them.

CHARLES FLACK.

Cholmondeley Castle Gardens.

SOUTH LODGE: BEAUTIFUL WATER SCENE IN WILD GARDEN.

Early Antirrhinums. — By sowing seeds now under glass of one of the named bedding varieties of antirrhinum, first-rate plants that will flower early may be had for bedding out in May. After the seedlings are up, the plants should have comparatively cool treatment, and should have their tops pinched out if they get at all leggy. By the beginning of May the plants should be established singly in small pots, and should be then hardened off in a cold frame preparatory to planting outdoors.—E. J. K.

Splitting up Phloxes.—The transformation effected in an old and neglected phlox clump by breaking it up and replanting in well dug and dunged ground is one of those things which must be seen to be believed. The flowers are quite doubled in size, while the erstwhile flat-topped flower trusses assume a deep, pyramidal shape. In splitting up a clump, only the best of the outer portions should be used, and these should be so reduced in size that only two or three shoots are left on each. If such pieces are planted in a triangle, 1ft. apart, they will make a brave display the first season, and a better one still the next.—E. J. K.

KNIPHOFIA JOHN BENARY.

The increased interest taken of late in the development of the informal garden—a garden in which bold grouping becomes almost a law—has opened up a use for bold-habited plants that have the power of making headway under adverse conditions, and will give a strong colour note which distance cannot well depreciate. Kniphofias (torch lilies) are invariably chosen for grouping, but a difficulty arises, if I may judge from numerous enquiries, as to which of the hundred or more varieties is the best for this purpose. Typical K. aloides, the common torch lily, lacks many good features a garden plant should possess; it is coarse, its leafage is abnormally strong when compared with hybrids, and when growing in poor soils the flower spikes are poor and ill-developed.

The old-time hybrid, named John Benary, studied in competition with more recent productions, proves the best for general display. Its leafage is moderately strong, and held sub-erect. Its flower spikes are the longest of all red torch lilies, and the colour note—a rich fiery red—is quite unsurpassed. It is a floriferous plant withal; I have counted thirty spikes from one three-year-old clump, all models of perfect finish, there being little trace of the glaucous tint that characterises many torch lilies, little also of the pale orange shade many display when fading, and the disfigurement of a mass of clinging spent flowers is wanting, the plant producing but few seeds. I once collected and germinated a handful of seeds of this variety, and the plants flowered in due course. I have no hesitation in declaring John Benary the best coloured tritoma I have seen; the seedlings it gave me probably the worst.

G. B. MALLETT.

WORK FOR THE WEEK.

◆

THE ORCHID HOUSES.

SMALL SEEDLINGS.—There can be no question but that the treatment afforded in the early stages of growth has a very material bearing on the satisfactory development of seedling orchids, especially if we have in view the production of flowers within a limited time from sowing the seeds. Those who consider natural versus artificial conditions, will find that to follow Nature's laws in respect to the usual seasons of rest and growth will result in a period of from ten to twenty years elapsing before flowering plants are produced. The more rapid flowering of seedling orchids during late years has been accomplished by growers realising that, after all, orchids are but plants, and require practically the same conditions and treatment as other kinds, and so, by keeping the seedlings in an active state of growth until the flowering stage is reached, they have found a very considerable advantage over the old system.

YOUNG PLANTS taken from their seed beds last spring and summer will now be found more or less active. With such kinds as cattleyas and allied genera it is advisable to examine their condition, and, should the compost be in any way decomposed, or the plants require more rooting space, repotting should be attended to without delay. The pots used must be clean. For drainage purposes use just a single potsherd over the hole at the bottom of the pot, and fill the pots to about one-half their depth with chopped bracken roots. The potting compost consists of about two-parts fibrous orchid peat, and the remaining portion of about equal parts of broken oak or beech leaves and chopped sphagnum-moss, with sufficient silver sand added to render the whole porous. We use such a compost for plants of this class in practically all stages, but as the plants grow older and advance towards the flowering stage we use coarser material. It will be scarcely necessary for me to add that, to keep the plants in an active state at all seasons of the year, growing conditions must be maintained. No hard and fast lines can be laid down, because of the varied conditions that obtain, so the cultivator must be guided to success by the particular circumstances with which he has to deal.

SMALL PLANTS from late summer and autumn sowings may now be taken from their seed-beds and pricked out, several together or separately. I advocate pricking off separately if possible, because the plants can be the more easily treated. Small pots are procurable from an inch in diameter, and these may easily be plunged into larger pots, several together if necessary, so that they will occupy little or no more room than when pricked out several together in larger pots. In affording root moisture care should be observed to ascertain that the water used be as warm as the temperature of the house.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

ACHIMENES IN BASKETS.—These beautiful plants well deserve more extensive cultivation in baskets, for which purpose, by reason of their free-flowering and general habit they are so admirably adapted. To provide successional batches of plants in flower the tubers will require to be started at intervals commencing with the first batch early in February. Prepare an open porous compost of loam and peat in equal parts, with about one-sixth part of charcoal, coarse sand, and dried sheep manure. Prepare the baskets with a lining of sphagnum moss, and fill up with the compost to within an inch of the surface. Place the tubers about an inch apart evenly over the surface, and cover with rather fine soil. The number of tubers used will be determined by the size of the baskets. Give sufficient water to settle the soil, but no more until the plants are growing freely. Suspend the baskets from the roof of the intermediate stove; this position will insure a strong short-jointed growth so essential to success.

BOUGAINVILLEAS.—For general decorative purposes Bougainvillea glabra still retains its high position, and is most valuable for covering back walls or over the roof of the stove. In either position, if allowed sufficient room for the development of its beautiful drooping floral sprays it produces a charming effect, and is most useful for cut flowers. Bougainvilleas do not require a long season of rest, and may now be pruned back and started into growth. They are all strong-rooting, and require a fair amount of root room to allow the full development of their characteristics. Hence they succeed best in a compost which will remain in good condition for a considerable period. An excellent compost is prepared with two parts of strong fibrous yellow loam, one part of peat, and sufficient charcoal and sand to keep it porous. After the plants show signs of growth those in pots should have the greater part of the old soil carefully removed from the roots and be repotted, using pots a few sizes smaller. Firm potting is indispensable to produce short-jointed growth.

STEPHANOTIS FLORIBUNDA. — There are few stove plants more worthy of the popularity enjoyed than this easily-grown and profuse blooming stephanotis. Having a naturally twining habit it succeeds best as a roof climber, a position which displays the sweet-scented blooms to advantage. If it is desired to grow the stephanotis in specimen form on a balloon-shaped trellis, the plants ought to be given a position near the glass or have the growths trained on strings over the roof. In this way the growths can be readily removed from the roof when fully developed, and trained into the desired shapes. Stephanotis succeed best in strong soil, similar to the compost recommended for the bougainvilleas, and also require a firm potting. Plants which are growing in large pots may have a few inches of the old soil removed, and top dressed with soil as recommended for potting.

WATERING AND VENTILATION.—Careful attention in watering of newly-potted plants is essential, and it must be remembered that too liberal applications to the roots at this stage will be disastrous. Judicious and thoughtful manipulation of the ventilators is also very important as fluctuations in temperatures must be avoided. Care must be exercised in the regulation of the hot-water apparatus, more particularly when the sun is likely to be strong, or much damage will be caused to the young foliage.

SYRINGING AND DAMPING of the stove will require to be done more frequently than has been necessary for some time past. All permanent borders for stove climbing plants should be given attention, and a few inches of the old soil replaced with a fresh rich compost.—John Donoghue, Bardon Hill Gardens.

FRUITS UNDER GLASS.

VINE EYES. — A few varieties of these should be started, more especially Black Hamburgh and Foster's Seedling, for planting in new early vineries and for stocks on which to graft almost any other grape. Select stout plump buds which were well ripened last season. They should be free from all insects, and, when prepared, be placed singly in small pots filled with good sandy soil. Plunge these in a good bottom heat. As soon as the growth appears wood-lice will attack them, and soon destroy the whole stock, unless a close watch is kept and the necessary precautions taken.

LATE VINERIES.—All cleaning and top-dressing should be finished by now, and the vines may be started as required. Muscats take somewhat longer to finish than the other varieties, and they should be given a longer time. The glass should be washed on the outside as the vines break, especially where fogs are prevalent.

MELONS.—The house for these should have the necessary preparation previous to planting. Keep the hotbed and soil well up to the glass, as the plants will not have so far to grow before they can fruit. A mixture of good fresh cut turfy loam, wood ashes, and plaster rubble will be the most suitable for forming the beds, and a little soot may be added. For early crop plant fairly close together, about two feet apart being best, and the width of soil should be eighteen inches, as these only require a moderate root run. In placing the soil on the bed it can be made to form a high ridge. If the plants are at all weakly, let them grow on in the pots for a short time longer For early supplies pots may be used, but I prefer planting out. If the sun is very strong they will, perhaps, require to be shaded during midday; a sheet of thin paper may be placed above each plant over the wires. This should not be done unless necessary as undue shading weakens them. Syringe paths, walls, and other things in the house when dry, and maintain a buoyant atmosphere and a temperature of 70 deg. at night, and from 75 to 80 deg. by day. Very little ventilation will be required for a time, especially if the house is well charged with moisture.

EARLY PEACH AND NECTARINE HOUSE.—After the crops are set a rise of 5 deg. may be given at night and day, but a steady temperature must be kept at all times. If the border will not require watering till after the stoning period so much the better, disbudding must be done gradually; syringe and shut the house up early. A very light fumigation should be given when the swelling of the fruit can be seen to keep away greenfly.

EARLY STRAWBERRIES. — Plants that are well set with fruit may be given some weak liquid manure. Sheep manure forms one of the best liquids. Place it in a bag in a tub, and it should be stirred round after watering every day so that it will be clear the following day, it being important that no sediment settles on the surface of the soil. —A. B. Wadds, Paddockhurst Gardens, Sussex.

THE KITCHEN GARDEN.

ASPARAGUS FORCING.—Batches of this delicious vegetable may still be started on a mild hotbed in frames, being careful to select the strongest and most prominent crowns. By careful management of ventilation and watering, good succulent heads will be produced, and these should be cut daily as they become ready, and placed with their ends in water.

PERMANENT BEDS.—By erecting a rough framework over the whole or part of a bed, and placing some spare lights over it now, and giving the bed a few waterings with liquid manure, good asparagus will be ready for cutting quite three weeks in advance of the unprotected beds.

BRUSSELS SPROUTS AND CABBAGE. —A pinch of seed should now be sown in boxes of each of these two most useful vegetables. Sow thinly, so that the seedlings may have plenty of room to develop. If large quantities are required, a frame will be the most suitable place to make the sowing in, but usually for the first batch only a small quantity is required.

CELERY.—This is always appreciated, and, where it is required early, seed should now be sown in boxes or pans, in light rich soil. Cover the seeds very lightly, and water through a fine rose. Place the seed in a structure in which a temperature of 55 deg. is maintained.

ESCHALLOTS.—These should now be planted in good rich soil which has been well worked and manured. Place the bulbs a foot apart in rows. The small cluster variety is a good one for pickling, and the Russian variety grows to a large size, and is most serviceable for flavouring purposes.

EARLY CAULIFLOWERS.—Young seedlings from last month's sowing will now require to be pricked off into other boxes, or on a slight hotbed. Another sowing may be made for succession, and those planted in cold frames in the autumn must have all the air that is possible to give them. If a few are potted up in eight-inch pots they will give some early heads.

JERUSALEM ARTICHOKES. — Where there is a considerable demand for these it is prudent to devote a large quarter to them and give good cultivation. If the soil is in a fit state, they should be planted without delay. Select fair-sized tubers, and plant them in rows two feet asunder. The newer white variety seems to be the sort most appreciated. To obtain good-sized tubers it is necessary the ground should be liberally manured.

STACHYS TUBERIFERA.—The tubers of this vegetable are of excellent flavour, and are liked by many when properly cooked and served. The tubers also make a change late in the autumn, when there are not many varieties of vegetables to select from. It usually commences to grow very early in the year, and therefore it is important to plant the tubers at once. Their brittle growths are liable to be broken off during planting if they are far advanced. The same treatment as advised for the Jerusalem artichoke will suit this also, except that they can be planted closer together: good distances are fifteen inches from row to row, and a foot apart from each tuber.

RHUBARB.—Some of the large roots growing in permanent quarters may now be covered with boxes or old barrels, and have a good thickness of long litter or leaves placed round them. The mild warmth from the fermenting materials will stimulate the growth, and the result will be a good crop of full-sized sticks. These will be of better flavour and have a good colour when brought on gently, as in this case.

BROAD BEANS.—A few single rows of these should be planted for succession, choosing an open quarter, and where the soil is a little strong it will suit them quite as well.—T. W. Birkinshaw, Hatley Park Gardens, Sandy.

SUTTON'S CYCLAMEN.

Twenty years or so ago the superior cultivation of cyclamens was regarded as a matter of unusual interest and importance, and the man who could grow big plants from old corms and flower these freely for several years in succession was regarded with some amount of awe. Cyclamens were a test of cultural ability in those days, and the horticultural Press of that time will show how great was the interest that surrounded these "perennial" plants. Following on this period was one wherein the cyclamens took a secondary place; forced bulbs and plants came very strongly into favour for winter-flowering, and somewhat pushed the elegant cyclamens out of their former high place. The raising and cultivation of late-flowering chrysanthemums also helped materially in this direction.

Fortunately, during this period the seedsmen who knew the value of cyclamens did not cease their efforts to improve the size, and colour or purity of the flowers, and the habit of the plants. The market growers did not lose their faith in cyclamens, though they dropped primula culture in most cases. The cyclamens carried well to market, and lasted well when sold, hence they were always more or less in demand. However, the private grower, whose name is legion, has recently awakened to the fact that cyclamens are at just as valuable as late chrysanthemums and forced bulbs, perhaps a trifle better, and so during the past five or six years there has been a renaissance of cyclamen cultivation. Now, however, the grower rarely cultivates his plants for more than one season, and scarcely ever more than two seasons.

Messrs. Sutton and Sons, of Reading, have done splendid work in both the improvement and the cultivation of these charming winter flowers. They sow the seeds in pans in the late autumn, placing these seeds carefully an inch apart in the soil—which consists largely of sterilised leaf-mould. A warm greenhouse temperature suffices, and the seedlings are kept near the glass, and at this season of the year, February, they are sturdy youngsters, soon to be potted up singly, and they will give a gorgeous display of extremely [illegible] and elegant blossoms from about Christmas-time until the end of March next, just as their predecessors are doing now.

All the world, the horticultural world at any rate, knows that the Messrs. Sutton have done wonders in carefully selecting and fixing the various colours of the ordinary type of cyclamens. Their Salmon Queen is an exquisite shade of salmon pink, and one that is seen at its best under artificial light. A few plants in a group or a few flowers in small specimen glasses give a very pleasing touch of colour to the decoration of a home. Vulcan, the fiery crimson, seems never so bright as when the rays of the setting sun fall upon the conservatory, room, or house in which it is flowering, though here again, just a few blooms in small glasses are very handsome on the dinner table. Phœnix is a cherry red variety that gives an intermediate shade of colour, and it has its favourites. As a white, this firm's White Butterfly is difficult to surpass, and it has the merit of being one of the most floriferous varieties known.

But not content with improvement in this direction, the Messrs. Sutton and Sons, some years ago, selected out a giant strain of cyclamens, just as they have selected out, perfected, and fixed a giant strain of Chinese primulas. In these giant cyclamens the flowers are of wonderful size and substance, and when batches of these, in their several colours, are seen in perfection, as they may be at present at Reading, they so surpass the ordinary type that one expects to find them much more extensively grown in the near future than at present. However, high cultivation, close breeding, and selection have their drawbacks, and the drawback in connection with giant cyclamens is one for the raiser to trouble about rather than the grower. Nature exacts her toll, and so, while she cannot stay the hand of improvement in respect to increased size and substance in the flowers, she steps in a little later and makes the raiser pay for his success by limiting the seed crop. The same thing has occurred here as with the giant primulas; extraordinary size and substance are grudgingly yielded at the expense of seeds. There is, therefore, no very near prospect of any material reduction of the price of seeds of these giant strains; indeed, they are only maintained by incessant vigilance.

The giant cyclamens are Giant White, Giant Cherry Red, Giant Mauve, Giant Rose Pink—a delightful shade of colour, Giant Salmon Pink, a large counterpart of Salmon Queen; Giant Crimson, and Giant Purple. Giant Crimson and White is a beautiful variety, with pure white flowers that are crimson at the base.

Another type of cyclamens upon which the Messrs. Sutton and Sons are expending a great deal of care is the fringed group. The old Papilio varieties do not open kindly, and when they open they mostly hang their heads as though ashamed. But at Reading this has been altered, and a fine series of fringed varieties is in the making. Already a fine strain of mixed colours is offered, and in this the flowers are erect, and have their petals more or less fringed. But in the special selections that have been made from this strain there are some of the most beautiful cyclamen flowers we have ever seen. One blush, crimson-based flower, with petals as large and broad as any seen in the finest giant forms, and all exquisitely frilled and fringed, is so beautiful that one is tempted to foretell an eclipse of the smooth type. In any case, there is ample room for these newcomers, whether they be self-coloured, shaded, or tipped and striped with colour. There is little doubt, however, that, thanks to the enterprise of the Reading firm, there will soon be a greater range of colour and form in these delightful winter flowers than was thought possible only a few years ago.

Not only are cyclamens making a brave show at Reading just now, but Chinese primulas are particularly fine. As with the cyclamens, so with the primulas, every possible care is taken to keep the varieties pure and true to character, whether it be the blue Czar or the charming Duchess, or the more plebeian Star varieties.

MESSRS. SUTTON AND SONS' FINE STRAIN OF GIANT CYCLAMEN.
As grown in the Trial Grounds of the firm at Reading, and arranged in blocks of distinct colours.

Increasing Choice Michaelmas Daisies.—One does not, as a rule, get a very tremendous plant when buying a new Michaelmas daisy, and, after the plant has revealed its merits by flowering, there may come the desire to increase it. The best way to do this is to detach the young growths early in spring, each with, if possible, a few roots attached, and place them singly in small pots. These pots should then be stood in a close cold frame, and the plants encouraged to make all the growth possible. If potted up now nice stuff should be available for planting out again in April in the garden. If required for flowering indoors, the plants should be repotted.—E. J. K.

NEW BOOKS.

ROSES: THEIR HISTORY, DEVELOPMENT, AND CULTURE.

By the Rev. Joseph H. Pemberton. (Longman, Green, and Co., 39, Paternoster Row, London.) Price, 10s. 6d.

The Rev. J. H. Pemberton is so well known as a keen and successful rosarian and able writer that we feel assured we shall not surprise our readers when we state that the work now before us is of such remarkable merit as to be one of the most valuable contributions to the literature of the rose that has yet been made by an amateur. From the day we first heard from Mr. Pemberton that he was busily engaged in the pleasurable, but by no means easy task of writing a book on roses, we anticipated with much interest and some degree of eagerness its appearance. Knowing how thorough is his knowledge of all that is associated with the rose and its cultivation and development, and well acquainted with his graceful style, we felt that we had full justification for expecting a work that would not only be widely different from the numerous books on roses that have been published within recent years, but that it would be of so high a character as to at once take a prominent position among the best of the works on the fascinating subject with which it deals that have been published. Our expectations were high, and it gives us much pleasure in stating that they have been more than realised. There is no other work with which it can be compared; it stands alone, a mine of information on roses and rose culture, with its treasures so placed that those who resort to it for advice can obtain it with the smallest possible amount of trouble to themselves.

The work is not only graceful in style and sound in teaching, but it is so comprehensive that all that relates to roses is dealt with so fully as to render it wholly unnecessary to refer to other books when making an endeavour to solve some difficult problem. In the interesting introduction we are taken back to the days when Mr. Pemberton was a child in petticoats, and admired the closely-packed nosegays of such old favourites as Duchess of Sutherland, Leopoldine d'Orleans, Félicité et Perpétué, and Aimée Vibert, which the old gardener to the family was fond of arranging. We are reminded of the time when he had a small garden all to himself, with three standard roses, which he had the pleasure of pruning. Mr. Pemberton briefly refers to his commencing to show roses in 1874, when in a class for twelve he obtained second prize. He also mentions that he has exhibited at every show of the National Rose Society, including the first held in St. James's Hall, where, in a class for twelve, in which there were forty competitors, he obtained the second prize. Nothing, however, is said of the champion trophies he obtained, or of the first prizes well-nigh innumerable he has won during the thirty-two years he has taken an active part in competitive gatherings. We admire the reticence of the author with regard to his successes, although we know that a sketch of them would have been most interesting.

The brightly written chapter on "The Rose, the Flower of England" is an excellent preparation for the substantial reading provided in the chapter on "The Botany of the Rose," by which it is immediately followed. In this the several parts of the plant and its flowers are scientifically, yet pleasantly described, and a synopsis of the several types, according to the classification of M. Crèpin, and an analysis of the known species are given. In the two succeeding chapters the species indigenous to this country, and the wild species of other countries are described with sufficient fulness to enable the reader to obtain a clear idea of their distinctive characteristics, and also to readily recognise them when in bloom. The chapter on the "Summer-flowering Roses" is of much interest, as also is that devoted to "Autumn-flowering Roses," the latter especially so because of the large amount of information relating to the development of the several classes it contains. The designation of the varieties that bloom but once, as summer-flowering, and those blooming throughout the summer and autumn is not particularly happy. The hybrid perpetuals, the hybrid teas, and the teas are usually at their best during the summer months, and consequently belong just as much to the summer as do the Cabbage, the Damask, and others that have a short season of flowering. Mr. Pemberton is not, of course, responsible for this division of varieties; he has simply followed the classification that has so long been used, and, while we should like to see a change made, there can be no doubt as to his having acted wisely in not attempting it in his book.

The remaining chapters are devoted to cultural matters, hybridisation, and the raising of seedlings, the prevention and eradication of insects and fungoid pests, exhibiting and judging. As the author is well versed in every detail essential to success in the cultivation and exhibition of roses, is sound in his views with regard to the creation of new varieties, and has the ability of readily imparting his knowledge to others the cultivator will have no difficulty in finding information upon every point about which he may be in doubt.

The book has for its frontispiece a coloured plate of the dog rose, and is illustrated with line drawings of the older types of roses and with pen and ink sketches of such operations as budding and grafting, the latter being the work of Miss Florence Pemberton.

LIST OF BRITISH PLANTS.

By George Claridge Druce, M.A., F.L.S. (Clarendon Press, Oxford). Price, 2s. 6d.

In the preparation and publication of the list of plants found either as natives or growing in a wild state in Britain, Ireland, and the Channel Isles, the secretary of the Botanical Exchange Club of the British Isles has rendered a service of immense value to botanists, and, indeed, to all who are interested in British plants. In the compilation of this work, which is the outcome of over thirty years' field work in every British county, the author has endeavoured to bring together all the plants which are natives of the British Isles, or which have been found in a wild state in them; that is, plants ranging from the most absolute natives to the merest ballast waif, and in this endeavour he has been remarkably successful. The names of the species, sub-species, and varieties are arranged under their several natural orders, in accordance with botanical usage, and by the employment of different types and a few marks the reader is able to at once see whether the plant is a native, a doubtful native, or an escape from cultivation. The authorities for the names and the counties in which the plants are found are given, and where the plant is an alien the name of the continent or country in which it is a native is indicated.

The "List of British Plants" contains 1,390 British species, 401 sub-species, 89 species somewhat doubtfully native, as the elm, 144 alien species now well established, and 940 alien species more or less fugitive. There are 1,430 varieties enumerated, as well as 259 hybrids. Of the 1,084 aliens, 751 are natives of Europe, 102 are Asian, 162 American, 6 Australasian, and 30 cultivated species. The British species are composed of 52 trees, 210 shrubs, 7 climbing shrubs, 1,020 perennials, and about 350 annuals. The work, we would add, has an excellent index, and is well printed.

LES PLANTES VIVACES DE PLEINE TERRE.

By Jules Rudolph. (Charles Amat, Librairie des Sciences Agricole, 11, Rue de Mézrèes, Paris.) Price, 5 francs, in paper covers.

An excellent book on the selection and cultivation of hardy perennials. It consists of about five hundred pages, and is divided into two parts, the first being devoted to a general sketch of their cultural requirements, and the second to the description of the finest of the hardy plants in cultivation, with particulars of their propagation, and the positions in the garden for which they are best suited. We fail to find some of the more noteworthy plants of recent introduction, but the book, nevertheless, is highly meritorious, and may be recommended to those lovers of hardy flowers who understand the French language. So good a book deserves a more substantial cover than one of paper.

LIVE STOCK JOURNAL ALMANACK, 1908.

(Vinton and Co., Lim., 8, Breams Buildings, Chancery Lane, E.C.) Price 1s.

The issue of this almanack for 1908 fully maintains its high position as a complete annual chronicle of the doings of the studs, herds, and flocks of the United Kingdom. The current issue contains upwards of fifty special articles dealing with the various classes of live stock, and is consequently a veritable mine of up-to-date information relating thereto.

VINTON'S AGRICULTURAL ALMANACK AND DIARY.

(Vinton and Co., Lim., 8, Bream's Buildings, Chancery Lane, London.) Price, 1s.

In a new and improved form, this well-known and excellent year book for farmers and landowners has just been issued. The size has been altered, while the number of pages have been considerably increased. The main feature, however, is the inclusion of a diary for the year, with cash receipt and expenditure accounts. A review of the agricultural year and a monthly calendar of the operations of the farm are given, with a very large and complete collection of statistics, tables, etc.

NEW PLANTS, ETC.

CYPRIPEDIUM F. SANDER.

This very bold and handsome cypripedium, of unrecorded parentage, has evidently descended from C. insigne. It has a rounded dorsal sepal with broad white apex and light green base, the central area being freely marked with brownish spots. The broad petals and full lip are greenish-yellow, shaded with brownish purple. A.M., R.H.S., January 28; Mr. Hopkins, gardener to Francis Wellesley, Esq., Westfield, Woking.

CYPRIPEDIUM FAIRRIEANUM COOKSON'S VAR.

Now that C. Fairrieanum is abundant in collections the species is found to vary somewhat in colouration. In the present variety the small flowers are of very dark hue. The dorsal sepal is almost wholly deep claret purple, a little white showing towards the base. The petals are also darker than usual, as also is the lip. A.M., R.H.S., January 28. Mr. Chapman, gardener to Norman Cookson, Esq., Oakfield, Wylam-on-Tyne.

CYMBIDIUM GATTONENSE.

A distinct hybrid, obtained by crossing C. Lowianum with the bold C. Traceyanum. It suggests C. giganteum. The lip is creamy white with brownish-red markings; the sepals and petals are bright yellow-green with thick red veins. A.M., R.H.S., January 28. Mr. W. P. Bound, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

NEPHROLEPIS EXALTATA AMERPOHLI.

This is a very pretty variety of American origin, and one that has become popular in the United States. As shown, it was much dwarfer than most of the new forms, but it lacks nothing in beauty. The fronds are densely plumose, and present an appearance best described as "mossy." The variety appears to have a deeper green colour than most of its near relatives, though this may be due to culture. A.M., R.H.S., January 28. Messrs. H. B. May and Sons, Edmonton.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at ninepence per line, the minimum charge being Five Shillings. Offices, 148 and 149, Aldersgate Street, London, E.C.

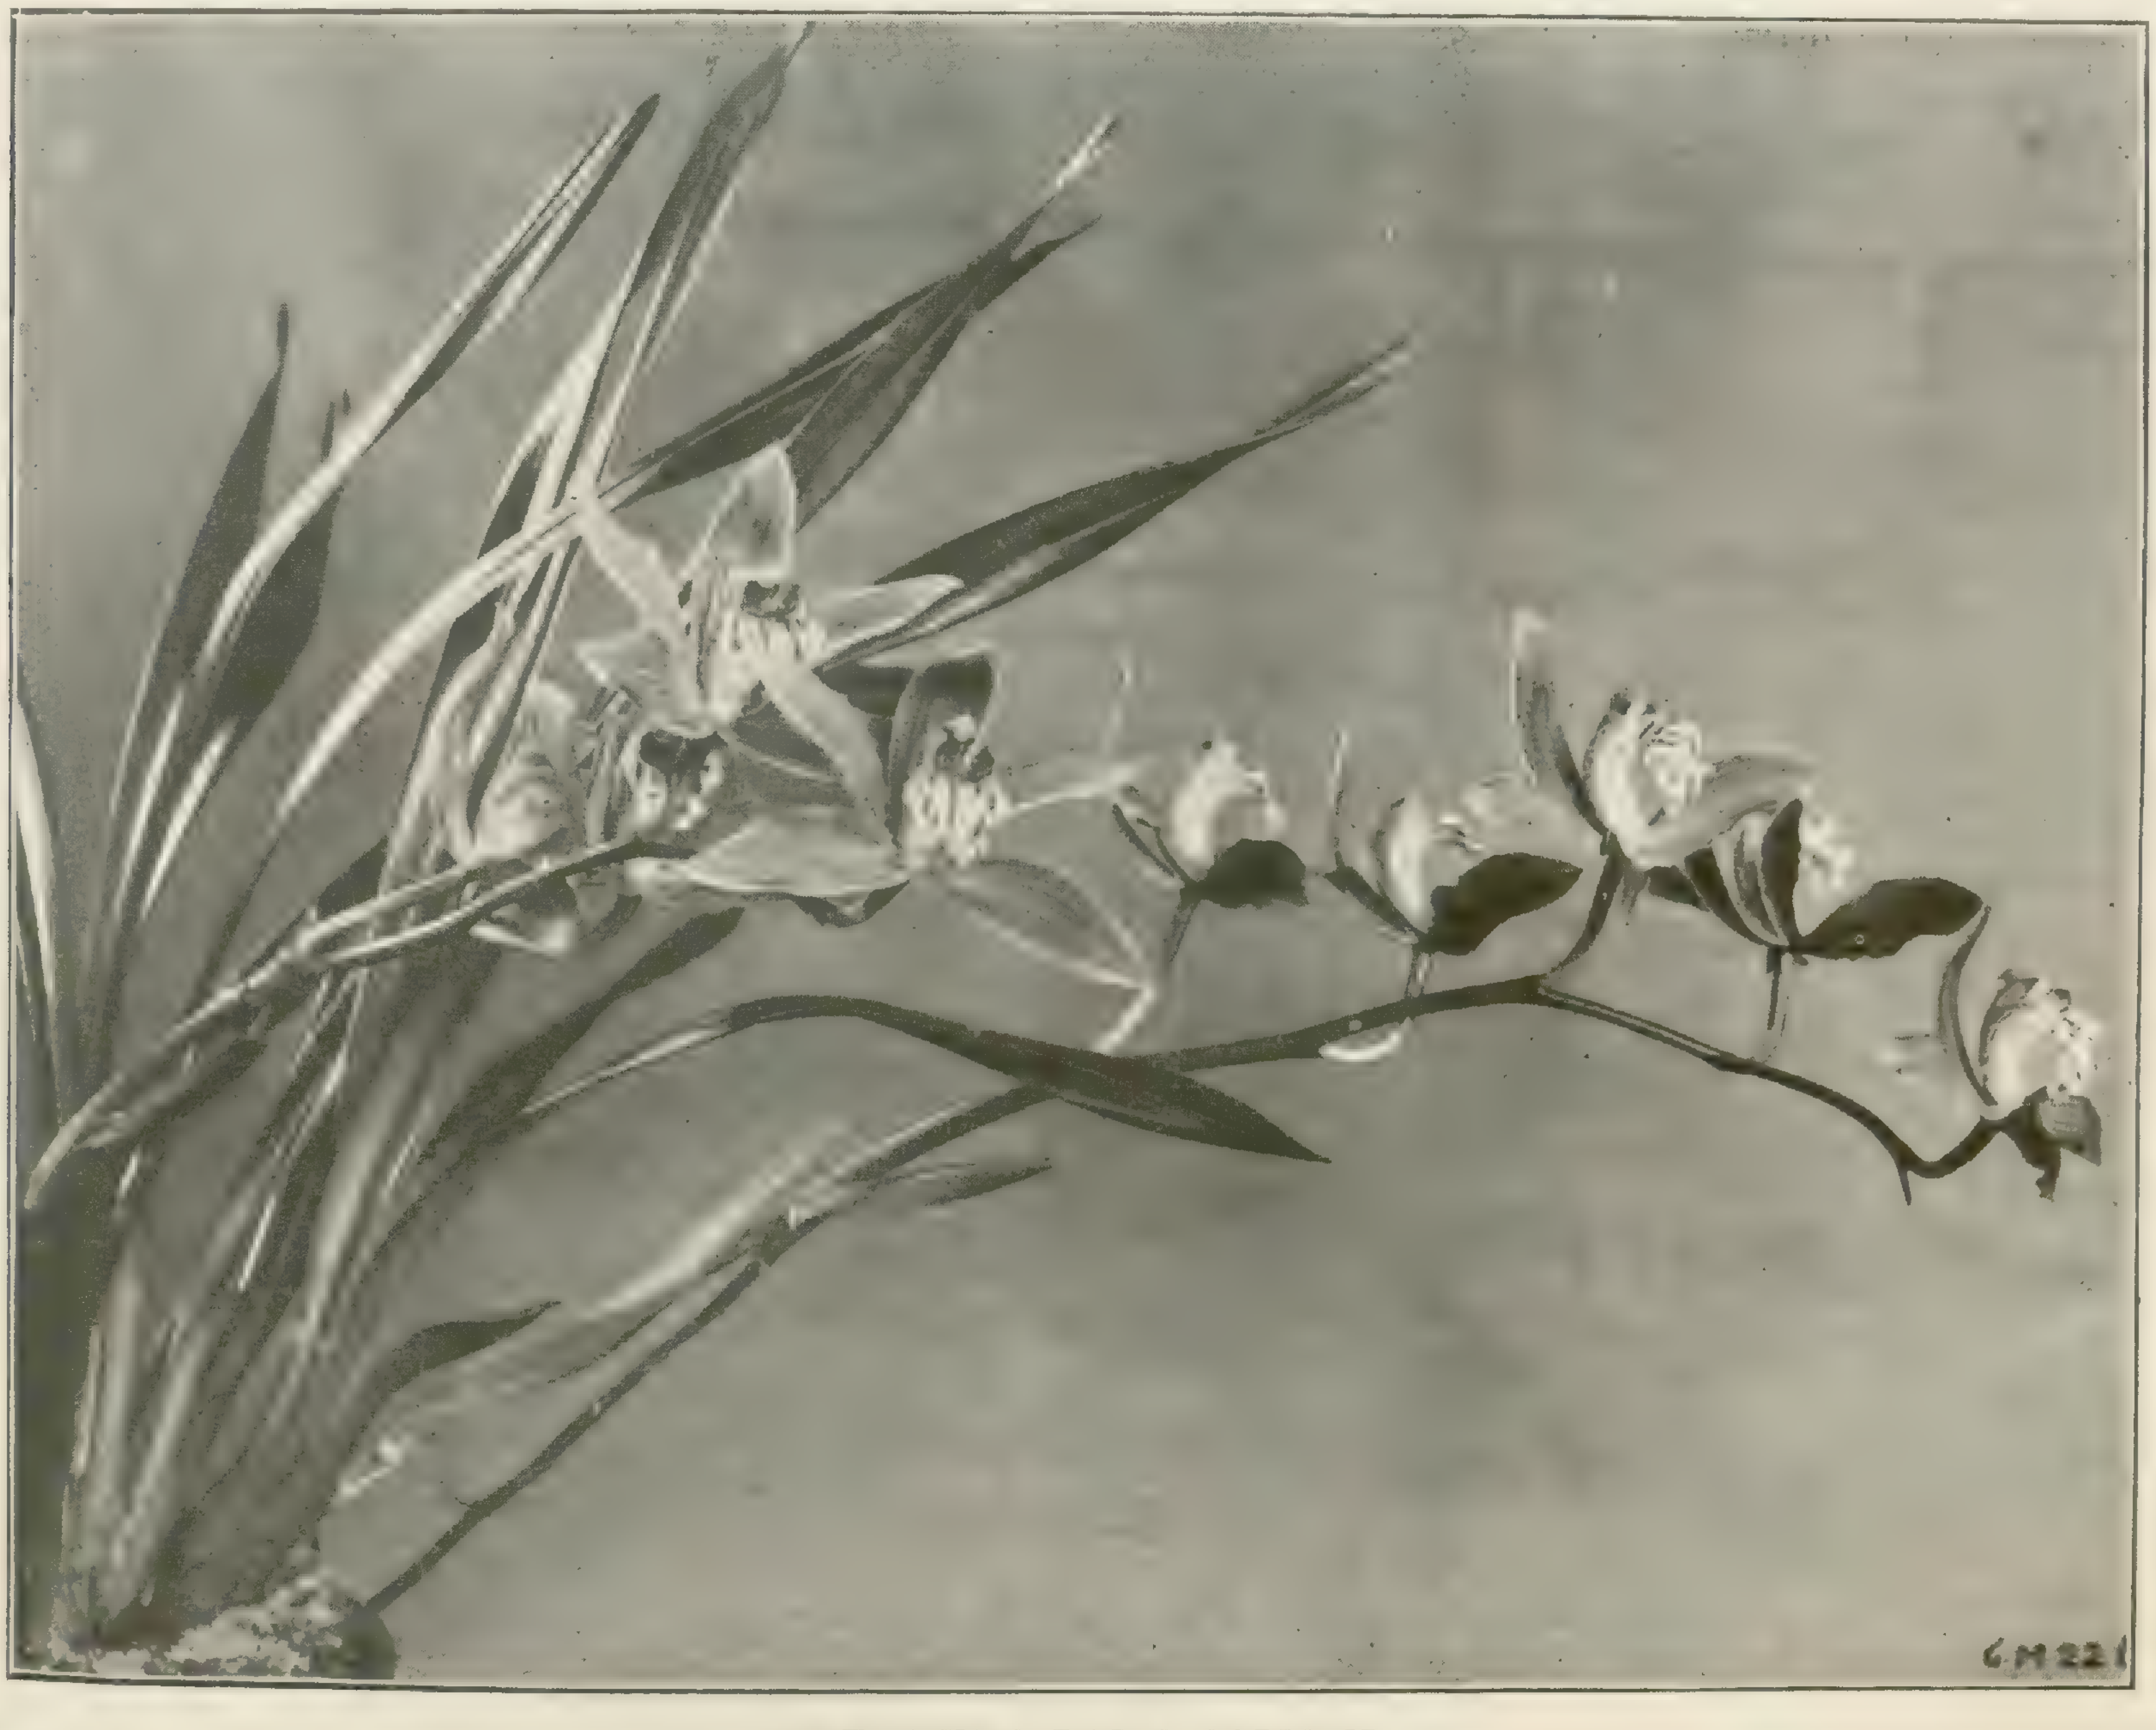
EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

On the occasion of the annual meeting there is always a very fine display at the Royal Horticultural Society, and February 11 was no exception to the general rule. Orchids, hardy flowers, forced shrubs, primulas, potatoes, oranges, and carnations were the chief features of a fine exhibition that was well attended.

FLORAL COMMITTEE.

Messrs. Sutton and Sons, Reading, made a fine display of primulas, filling a long table with their special varieties, such as The Czar, Giant Crimson, Giant Pink, Improved White Fern Leaf, Royal White, Reading Blue, Crimson King, The Duchess, Giant Salmon Pink, Snowdrift, Coral Gem, and a group of Duchess hybrids. The deep purplish blue Czar is a fine variety, and it showed up well in the centre of the group. Mr. W. H. Page, Tangley Nurseries, Hampton, filled one corner of the hall in a very pleasing manner with Lilium longiflorum, L. speciosum, and carnations in pots; behind, on the an- [illegible] front. Mr. Page had tall vases of beautiful flowers of Enchantress, Mrs. T. W. Lawson, Harlowarden, Britannia, and other fine varieties of carnations, and also filled in the front with these fragrant blooms.



CYMBIDIUM LADY COLMAN.

A beautiful hybrid exhibited by Mr. W. P. Bound, Gatton Park Gardens, at the meeting of the Royal Horticultural Society on Tuesday last, when it received an Award of Merit. The flowers are very large, the sepals and petals are cream colour suffused with green, and marked with broken lines of red, and the lip is white marked with red.

Hardy and forced flowers were largely shown by Messrs. Wm. Cutbush and Son, Highgate, who staged most of their plants in rock garden form. They had Iris reticulata, I. sindjarensis, Tulipa Kaufmanniana, Saxifraga Griesbachi, Colchicum montanum, C. hydrophyllum, and other very interesting subjects. Their forced shrubs included Prunus triloba, Wistaria sinensis, lilacs, and magnolias. The same firm had also a very pleasing exhibit of the choicest winter-flowering carnations. The Chinese primulas shown by Messrs. H. Cannell and Sons, Swanley, were remarkable for the wonderful size and beautiful colours of the flowers; the several forms were not named, but the strain as shown is a splendid one. Messrs. H. B. May and Sons, Edmonton, contributed a most interesting exhibit of hardy ferns, showing fine forms of scolopendriums, lastræas, polystichums, etc.

Some splendidly-grown cyclamens were exhibited by the St. George's Nursery Co., Hanwell, a firm that fully understands the culture of these flowers. They staged fine plants covered with fine flowers. Messrs. Jas. Carter and Co., High Holborn, displayed Chinese primulas, submitting batches of Holborn Coral, Holborn Crested, Holborn Scarlet, Aurora, Carter's Princess May, and King Edward. From Messrs. J. Peed and Son, West Norwood, S.E., came batches of lachenalias, Primula obconica, and alpines. The Misses Hopkins, Mere Gardens, Shepperton-on-Thames, showed a small collection of hardy flowers, and their coloured primroses and hellebores were the chief features. Messrs. Barr and Sons, Covent Garden, sent up some handsome seedling hellebores, chiefly from H. colchichus; they also showed H. punctatus and H. fœtidus, and a set of early crocuses and irises.

Perpetual-flowering carnations were again largely shown by Messrs. Hugh Low and Co., Bush Hill Park, Enfield, this firm setting up large vases of fine blooms of the popular varieties, and batches of flowering plants in pots. Britannia, Mrs. T. W. Lawson, Enchantress, Aurora, White Perfection, Oriflamme, and Beacon. Besides these the Enfield firm had dracænas, Otaheite oranges, daphnes, and cyclamens. Mr. W. Seward, Hanwell, put up some beautifully-grown cyclamens, making a large group of wonderfully free-flowering plants.

From the Guildford Hardy Plant Company, Guildford, came a collection of hardy heaths and veronicas; the New Zealand V. Hectori and V. cupressoides were especially attractive. Mr. R. Sydenham, Tenby Street, Birmingham, showed tulips, hyacinths, and lily of the valley in undrained pots in fibre and shell mixture. Mr. G. Reuthe, Keston, Kent, displayed Cyclamen Coum, coloured primroses, early crocuses, Iris stylosa, I. reticulata, hardy heaths, camellias, and small plants of Himalayan rhododendrons.

The corner of the hall close to the gallery stairs was most delightfully filled by Messrs. R. and G. Cuthbert, Southgate, with forced flowering trees and shrubs. The group was composed of Azalea mollis, very finely flowered, Magnolia conspicua, Pyrus atrosanguinea, Prunus triloba, Staphylea colchica, and a suitable accompaniment of palms, ferns, and Japanese maples; a charming display.

Chinese primulas were finely shown, and well set up by Messrs. James Veitch and Sons, Chelsea; Brilliant King and Chelsea Favourite were particularly pleasing. This firm had also batches of Indian azaleas, freesias, the very useful Primula Kewensis, the fragrant Cheiranthus Kewensis, and the blue Coleus thyrsoideus; they also had a group of the pale-fruited Aucuba japonica fructoalba. A collection of semi-double primulas in various colours was shown by Mr. W. W. Palmer, Andover, Hants. Ornamental kales were exhibited by Messrs. Barr and Sons, Covent Garden.

A beautiful exhibit of perpetual-flowering carnations was set up by Messrs. James Veitch and Sons, Chelsea; Victory, Mrs. H. Burnett, Fair Maid, Winsor, Fiancee, Beacon, and Rose Pink Enchantress were all very finely shown. Freesia Chapmanni, the bright yellow form, raised by Mr. H. Chapman, Rye, was admirably represented; there were also a number of very pretty seedling freesias in various colours, and a few new irises of the reticulata type. Mr. Grandfield, gardener to E. A. Hambro, Esq., Hayes Place, Hayes, set up a large exhibit of cyclamens and a splendid large-flowered strain of Primula obconica.

Hardy ornamental trees and shrubs, chiefly those with variegated foliage, were staged by Mr. L. R. Russell, Richmond. Conifers of a distinctly ornamental character were shown well by Messrs. J. Waterer and Sons, Bagshot; they had Pinus flexilis, Abies balsamica hudsonica, Abies excelsa aurea, A. ajanensis, and A. concolor in the display. Varieties of Helleborus orientalis, with Primula Forbesi, hardy cyclamens, Corydalis thalictrifolia, etc., were contributed by Messrs. T. S. Ware, Lim., Feltham. A very handsome set of Himalayan rhododendrons, all from the open ground, was brought up by Mr. R. E. Gill, from Tremough, near Falmouth; R. barbatum, R. Mrs. H. Shilson, Henry Shilson, and the seedlings were the chief varieties, but the size of the flowers and their colours attracted a great deal of attention.

ORCHID COMMITTEE.

Mr. G. G. Whitelegge, gardener to J. Bradshaw, Esq., The Grange, Southgate contributed a bank of orchids, in which the white forms of Cattleya Trianæ, such as C. T. alba, C. T. Esmeralda, and C. T. Adonis were prominent. Other good things were Odontioda Bradshawiæ, with a spike of twelve blooms, the finely formed Cattleya Trianæ The Premier, Lycaste Skinneri Orion, Cymbidium Hookerianum, a fine Odontoglossum Harryano-crispum, and Cymbidium Wiganianum. M. Maurice Mertens, Mont St. Amand, Ghent, brought over a few good cypripediums, and some delightful odontoglossums of Harryanum parentage. Messrs. Heath and Son, Cheltenham, showed cypripediums, Cattleya Percivaliana, and Dendrobium Wardianum.

A bold group of orchids came from Messrs. Cypher and Sons, Cheltenham. Cypripediums figured largely, but the group also contained some good odontoglossums, white Lælia anceps, Angræcum sesquipedale, Cattleya Trianæ varieties, and Cymbidium Winnianum. Messrs. Moore, Lim., Rawdon, Leeds, submitted a number of cypripediums, Odontoglossum Insleayi, Ada aurantiaca, and some white ground O. crispums. Messrs. Stanley and Co., Southgate, sent a small group of cattleyas and cypripediums.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, had a small group of orchids, and here the leading subjects were Cattleya Percivaliana, Dendrochilum glumaceum, and cypripediums. Messrs. Sander and Sons, St. Albans, had in their group of orchids some good forms of Cattleya Trianæ, cypripediums in variety, Vanda Watsoni, and the curious Barlia longibracteata. Messrs. Charlesworth and Co., Heaton, Bradford, had a number of graceful odontoglossums, Odontioda Bohnofæ, Lycaste Balliæ, Lælio-cattleya Myra, L.-c. luminosa, Cattleya Octave Doin, C. Empress Frederick, and other fine things.

Mr. Ballantine, gardener to Baron Schroder, The Dell, Egham, showed two fine plants of Odontoglossum coronarium brevifolium, one carrying five and the other six spikes. Odontoglossum Lambeauianum Lyoth, with brilliant red and blush flowers, was shown by Messrs. Charlesworth and Co. Mr. W. P. Bound, gardener to Sir J. Colman, Bart., Gatton Park, Reigate, showed a group of home-raised orchids, that included phaio-calanthes, spathoglottis, Cymbidium Lady Colman (A.M.), and the very interesting and beautiful Dia-cattleya Colmanæ (A.M.), the latter the result of crossing Diacrium bicornutum and Cattleya intermedia nivea.

FRUIT AND VEGETABLE COMMITTEE.

One of the most wonderful exhibits of potatoes ever set up was staged on this occasion by Messrs. Sutton and Sons, Reading. The attractiveness of the exhibit was beyond question, while its interest and educational value were both very high. There were 183 dishes of beautiful exhibition tubers, representing all the leading varieties, and there were 118 dishes of "seed" potatoes. The collection of tubers of species, hybrids, and rare varieties was exceptionally interesting, and we regret that in the present issue limits of space prevent further reference to this Gold Medal group.

Mr. Roupell, West Norwood, showed dishes of well-kept Smart's Prince Arthur, Newton Wonder, and Chelmsford Wonder apples. Messrs. T. Rivers and Son, Sawbridgeworth, Herts, set up quite an orange grove along the front of the stage; the plants were of various sizes, but all were carrying fine crops of fruit, while in the front centre of the group there was a quantity of picked fruits. This method of growing oranges in pots is one to be commended on the lines of orchard house fruits.

AWARDS OF MERIT.

To Lycaste Skinneri Orion, from Mr. J. Bradshaw, The Grange, Southgate; Cymbidium Lady Colman, and Dia-cattleya Colmanæ, from Mr. Bound, gardener to Sir J. Colman, Bart., Gatton Park, Reigate; Sophro-lælio-cattleya Antiochus rubra; and Cyclamen Salmon King, from Messrs. Hugh Low and Co., Bush Hill Park, Enfield.

MEDALS.

Gold.—To Messrs. Sutton and Sons, Reading, for potatoes.

Silver-Gilt Flora.—Mr. Whitelegge, gardener to J. Bradshaw, Esq., Southgate; Messrs. J. Veitch and Sons, Chelsea; Mr. W. H. Page, Tangley Nurseries, Hampton.

Silver-Gilt Banksian.—Messrs. H. Cannell and Sons, Swanley; Messrs. R. and G. Cuthbert, Southgate; Messrs. Sutton and Sons, Reading (primulas); Messrs. H. Low and Co., Enfield (carnations, etc.); Mr. W. Seward, Hanwell.

Silver Knightian.—Messrs. T. Rivers and Son, Sawbridgeworth.

Silver Flora. — Messrs. W. Cutbush and Son, Highgate; Mr. E. A. Hambro, Hayes; Messrs. H. B. May and Sons, Edmonton. Mr. R. E. Gill, Tremough, Cornwall; Messrs. Sander and Sons, St. Albans; Mr. Ballantine, gardener to Baron Schroder, The Dell, Egham.

Silver Banksian.—Messrs. Stanley and Co., Southgate; Messrs. H. Low and Co., Enfield (orchids); Sir Jeremiah Colman, Bart., Reigate; Messrs. Moore and Co., Rawdon, Leeds.

Bronze Banksian. — Mr. L. R. Russell, Richmond; Messrs. T. S. Ware, Feltham; St. George's Nursery Company, Hanwell; Mr. Roupell, Harvey Lodge, Roupell Park, Norwood.

ANNUAL MEETING.

In the unavoidable absence of Sir Trevor Lawrence, Bart., the treasurer, J. Gurney Fowler, Esq., presided at the annual meeting, which was held during the afternoon in the lecture hall. The hall was filled to its utmost capacity, and with so satisfactory a report and financial statement as were presented by the council, it is not surprising the proceedings should have been comparatively short and of the most pleasant character. The report was taken as read, and

The Chairman, in moving that it should be received and adopted, passed under review the work that had been accomplished both in London and at Wisley during the past year. He referred to the splendid exhibitions that had been held in the Temple Gardens, Holland House, and the Horticultural Hall, to the continued success of the fortnightly meetings, and to the opening of the laboratory at Wisley. In dealing with the financial results of the year's work the Chairman showed that they were thoroughly satisfactory. They had, he said, been able to carry on their work in the most efficient manner, to make considerable additions to the invested funds, to set aside the sum necessary for depreciation both at Westminster and Wisley, and to carry forward a balance of between £6,000 and £7,000. The expenses of the "Journal" were, he said, comparatively heavy, but that was owing to their having published the report of the Hybrid Conference, and to their having provided for the cost of the part of the "Journal" now in the press.

Sir J. T. D. Llewelyn briefly seconded the motion for the adoption of the report and financial statement, and in the course of his remarks congratulated the society on having a fully equipped laboratory at Wisley in which to investigate the many scientific questions associated with horticulture.

Mr. H. J. Elwes, F.R.S., V.M.H., congratulated the society on the financial results of the past year, and expressed the opinion that a much larger sum should have been spent on the library. He thought also the library should receive more attention from the council, and that Mr. Hutchinson, who has charge of it, should be raised to the status of librarian. Mr. Elwes further expressed his opinion that the fund now being raised for founding lectures in memory of the late Dr. Masters should be devoted to the library.

The Rev. G. H. Engleheart, V.M.H., referred to the awards made at the fortnightly meetings, and said that, in his opinion, the medals were distributed too freely.

Mr. A. W. Sutton, V.M.H., said it was most important the medals should only be awarded for contributions of a high degree of excellence.

Rev. J. H. Pemberton suggested the monthly publication of the "Journal."

Mr. R. Wallace pointed out that the utmost care was displayed by the committees in the awards of medals, and as the result of raising the standard numbers of collections at each meeting received simply a vote of thanks.

The Chairman having briefly referred to the points raised, the Rev. W. Wilks said there was a grave objection to devoting the Masters' Memorial Fund to the library. The library was a memorial to Dr. Lindley, and was known as the Lindley Library, and, therefore, could not well be a memorial to Dr. Masters.

The chairman, having announced that under the bye-laws a ballot for officers and the four members of council was not necessary, a hearty vote of thanks was accorded him, and the proceedings were brought to a close.

Horticultural Club.

The annual meeting and dinner of this club was held at the Hotel Windsor on Tuesday evening. Mr. H. J. Veitch, V.M.H., presided at both functions, in the absence of Sir John T. D. Llewelyn through ill-health.

As is customary, the attendance of members was small at the annual meeting. The honorary secretary, Mr. E. T. Cook, having read the minutes of the previous annual meeting, presented the report and balance-sheet for the past year. Both were of a most satisfactory character, and were unanimously adopted, for the losses that had been sustained from deaths and resignations had been more than counterbalanced by the election of new members. During the year Sir Albert Rollit and Sir Frank Crisp had been elected vice-presidents. Reference was made to the papers that had been read at the monthly meetings during the year, and these, it was said, and properly so, were of a high order of excellence.

The several officers and members of committee were re-elected, and Professor Farmer was elected a vice-president.

At the annual dinner Mr. H. J. Veitch was supported by Sir Albert Rollit, Sir Frank Crisp, Mr. W. A. Bilney, and other gentlemen well known in horticultural circles, and there were about seventy members and their friends present, the proportion of ladies being somewhat larger than usual.

The Chairman, in proposing the toast of "The Horticultural Club," expressed regret that Sir John T. D. Llewelyn was unable to attend, and said that this was the first time since he was elected many years ago that Sir John had been absent from the annual dinner. He was very pleased to say the club was in a most flourishing condition, the number of members was well sustained, the financial position was most satisfactory, and the work of the past year had been most successful.

Professor Farmer responded, and in doing so directed attention to the immense value of the club in bringing scientific and practical horticulturists into close association.

Rev. J. H. Pemberton submitted the toast of "The Royal Horticultural Society," and in the course of his speech referred to the splendid work that is being done by the society, and expressed a hope that some day it would have a Rose Committee.

Sir Albert Rollit acknowledged the toast in a graceful manner, and said he regarded the success of the society as largely due to the combination of amateurs, practical growers, and business men.

The remaining toasts were "The Chairman," proposed by Sir Frank Crisp, "The Honorary Secretary," proposed by Mr. H. J. Veitch, and "The Visitors," proposed by Mr. W. A. Bilney, the last being acknowledged by Mr. P. Anderson Graham and Colonel Lewis.

The musical arrangements were under the direction of Mr. Frank Morrison, and these contributed materially to the evening's enjoyment.

Birmingham Gardeners' Association.

The spring session was opened on January 27 by the president, Mr. Walter E. Collinge, M.Sc., F.E.S., with an address upon "The Action of Frost on Plant Life."

There was a good attendance, and, after the minutes had been read, the Chairman introduced the lecturer, who remarked that ere long he would be leaving Birmingham, but said that whenever he might revisit the city he would certainly try to attend the association's meetings.

Adverting to his subject matter, Mr. Collinge stated that we were now rapidly approaching the season of the year when fruit growers and others stood in great dread of the early spring frosts. Almost every year thousands of pounds' worth of fruit and vegetables were ruined owing to the lack of protective measures. As is well known, the air contains moisture; at a considerable elevation this becomes condensed and forms clouds. If condensation takes place actively, and the temperature is above freezing, rain is produced, or snow if the temperature is below freezing point. When the moisture close to the earth is condensed at temperatures above freezing dew is formed; if below, frost is deposited. We may, therefore, define frost as the moisture of the air close to the earth's surface, condensed below freezing point temperatures upon plants and other bodies. Wherever frost is deposited, the plant or other body must possess temperatures below freezing point. In the case of plants the temperature is reduced by radiation, and the evaporation of moisture.

Mr. Collinge next indicated the conditions most favourable to frost, and the conditions under which it was less likely to do serious damage to plant life. The action and effect of clouds were described at some length, and likened to a blanket over the stratum of lower air. The action of frost on plants is to cause an expulsion of moisture from the inter-cellular spaces in the plant tissues, which causes drooping of the leaves, as the moisture is not replaced because the root is chilled. Apart from the advantages to be derived from geographical situation, the grower must depend upon artificial appliances, and very many and varied these are. Screens formed of cloth, laths, or glass, covering the plants with straw, smudge fires, and many other devices have been suggested. After examining these different appliances the essayist stated that, acting on his advice, an Evesham fruit-grower had recently patented a special stove and fuel, which, in his opinion, was far superior to anything yet put forward. It had been tried in Worcestershire, and it was found that twenty-one stoves per acre were sufficient to fight nine degrees of frost. One man was sufficient to ignite and look after such fires on twenty acres of orchard. The cost of fuel was about 15s. per acre, and the fires burnt about six hours. The inventor claims for these stoves that they not only warm the atmosphere, but that they also give off a good smoke, which acts as a screen, and so protects the fruit from the sun's rays. In the lecturer's opinion there remained little doubt that ere long British fruit-growers would be as successful as those in the United States in protecting their crops and trees from the late spring frosts, which would mean much to the fruit-growing industry of this country.

The foregoing is the gist of a lengthened, deeply interesting, and instructive address that gave rise to practical remarks, more or less coincidental with those of Mr. Collinge, and in which Messrs. Walter Jones, T. Humphreys, W. Gardiner, C. R. Bick, C. H. Herbert, and A. R. Christie, severally took part. A hearty vote of thanks was accorded Mr. Collinge. Several new members were elected. Mr. A. Webb, gardener to Byng Kenrick, Esq., Metchley Lodge, Edgbaston, was awarded a cultural certificate for three plants of Primula stellata.

Manchester Horticultural Improvement Society.

At the fortnightly meeting, held at the Memorial Hall, Albert Square, Mr. F. Robinson presided, and Mr. H. J. Clayton, consulting horticulturist, Wharfe Bank, Ulleskelf, York, gave a very interesting and instructive lecture on "The Culture of Hardy Fruit." The lecturer imparted some useful hints on the culture of these fruits, such as should prove valuable to the members present. Several members having spoken, Mr. Clayton was accorded a hearty vote of thanks for his lecture.

Reading and District Gardeners' Mutual Improvement Association.

One of the most interesting meetings held in connection with the above association was the one taken by Mr. T. J. Powell, of Park Place Gardens, Henley-on-Thames, who gave a practical demonstration on the artistic arrangement of flowers. The first object lesson placed before the members was the decorating of a dinner table. The table had been laid to seat twelve persons, complete with cutlery, glass, candelabras, and silver vases. The central display consisted of an arch around the pillars of which was trailed asparagus Sprengeri, intermingled with sprays of Gloire de Lorraine begonia. Under the arch was a splendid plant of Salmon Queen cyclamen. At intervals were placed smaller arches decorated with similar foliage and flowers. The whole presented a most charming effect in pink. By request Mr. Powell followed with the making of a lady's spray and gentleman's button-hole with violets, also a small hand bouquet with the same flower. When these had been finished the time had arrived for closing the meeting, and it was proposed, seconded, and carried unanimously that the meeting should be adjourned. Therefore, the subject will be brought on again towards the latter part of this session, thus showing that practical demonstrations are exceedingly popular, and tend to make such societies a benefit to both old and young members of the gardening profession.

Mr. H. Wilson, The Gardens, Lower Redlands, staged a magnificent collection of apples, consisting of the following varieties: King of the Pippins, Golden Noble, Annie Elizabeth, Blenheim Orange, Potts' Seedling, Warner's King, Bismarck, The Queen, etc. The association's certificate of cultural merit was awarded to the exhibit. A hearty vote of thanks was accorded to Mr. Powell for his lecture, to Mr. Phillips for use of glass and cutlery, and to Messrs. Bracher and Sydenham for candelabras, silver vases, etc.

Sutton (Surrey) Chrysanthemum and Horticultural Society.

The fourteenth annual meeting of this energetic society was held on Friday, January 31, at the Cock Hotel, Sutton, Mr. A. Spencer Jackson presiding, and a very satisfactory report was submitted. The balance-sheet showed receipts (including previous year's bank balance), £114 17s., and expenditure £105 10s. 7d., leaving a balance of £9 6s. 5d. in hand. The Aston Silver Cup for twenty chrysanthemum blooms, won outright at the last show, is being replaced by the generosity of Mr. E. J. Holland, C.C.

The election of officers for 1908 resulted as follows: Major E. F. Coates, M.P., re-elected president; Mr. A. Spencer Jackson, chairman; Mr. H. A. Cooke, hon. secretary and treasurer; and Mr. A. W. Southard was elected vice-chairman. Mr. C. Osman, who had occupied the vice-chair for many years, retires with the thanks of the committee and members. Messrs. T. E. Roberts and V. R. Bromage were added to the committee.

Liverpool Horticultural Association.

The adjourned annual general meeting of this association was held on Saturday last at the Common Hall, Liverpool.

The meeting was adjourned to enable a statement of the accounts and a circular to be sent to all subscribers and members, drawing attention to the state of the finances of the society, chiefly through the loss in entrance fees at the autumn exhibition, which was held in a drill hall instead of the usual central St. George's Hall.

The grave position of the society only attracted a small attendance. Mr. T. Foster, who occupied the chair, briefly laid the position of affairs before the meeting, and requested the opinions of those present on the position of the association, and on the question of what shows should be held during the current year. A few offers of assistance were made, but, after considerable discussion, it was decided to hold only the autumn show.

The officers were re-elected, with their sanction to a considerable reduction in their salaries. A hearty vote of thanks was accorded to the officers and committee for their services during the past year.

Cardiff Gardeners' Association.

The fortnightly meeting of the above association took place at the Philharmonic Restaurant, Mr. H. R. Farmer presiding. The evening was devoted to "Questions" by the members. Many questions were put forward, and these created an interesting discussion. Some questions were: "What are the reasons we do not get better results from the hardy fruit garden?"; "Is there any remedy for the cucumber spot?"; "What are the advantages of summer and winter pruning of fruit trees?"; "What is the cause of Foster Seedling grapes cracking?"; "What is the best remedy for eelworm?"

These questions were thoroughly and practically discussed, with the exception of "cucumber spot," no one being able to suggest anything very effectual as a remedy.

The annual dinner of the society took place in the same building on January 29, when E. Batram, Esq., took the chair, and fifty members spent a most enjoyable evening. After dinner the usual toast list was gone through, and the members were entertained with a good programme of music.

Woolton Chrysanthemum Society.

The annual meeting was held at the Mechanics' Institute on Friday, the 1st inst., when Mr. Neil Gossage occupied the chair. The report gave evidence of a good year's work. The statement of accounts was also satisfactory, the income, including subscriptions, £77 17s. 6d.; advertisements, special prizes, and interest, £32 18s. The expenditure included prize money, £68 18s. 6d.; printing and hire of halls, £14 1s.; music, judges' fees, etc., £25 18s. 3d.; leaving a gain on the year's working of £1 17s. 9d., and making a total balance in the bank of £34 16s. 1d. Reference was also made to £3 15s. contributed to the Liverpool Auxiliary of the G.R.B.I. The officers elected are: Messrs. N. Gossage, hon. treasurer; R. G. Waterman, Woolton, assistant hon. treasurer; and W. D. Skinner, Gateacre, hon. secretary. A vote of thanks to the chairman terminated the proceedings.

Beckenham Horticultural Society.

On Friday week Mr. J. B. Hunter, of Elmhurst Gardens, Bickley, gave a lecture on "Peach Culture." There was a good attendance, and the practical instruction was very closely followed, and evoked a very lively discussion. A tree suffering from "silver leaf," under the charge of the lecturer, has been completely cured by lifting the roots and applying artificial manures liberally, i.e., Peruvian guano, basic slag, etc., and another case was made known in the discussion where it was said a cure was effected by a liberal application of lime to the roots. At the close a hearty vote of thanks was accorded Mr. Hunter.

Redhill and Reigate Gardeners' Society.

This Mutual Improvement Association held its fortnightly meeting, as usual, at St. Matthew's Parish Rooms, Redhill. A capital paper was read by Mr. W. Turnham (representative of the Reading Gardeners' Association) on "Trenching and its Advantages." A lively discussion ensued, and from it much valuable information was obtained. A very hearty vote of thanks was accorded Mr. Turnham for the admirable way in which he dealt with his subject.

GARDENING ENGAGEMENTS.

Mr. R. Armer, for several years foreman gardener, Scott Park, Burnley, has been appointed superintendent of the Weston-super-Mare Parks and Gardens.

Mr. Ernest Paiton, from Queen's Park, Burnley, succeeds Mr. R. Armer at Scott Park, under Mr. R. Murray, superintendent of Parks and Gardens, Burnley.

Cestrum (Habrothamnus) aurantiacum.—The qualities of this charming greenhouse plant are by many gardeners decidedly underrated. Its easy culture and vigorous free-flowering habit, strongly recommend it both for pot culture and for planting out in the greenhouse or conservatory. When trained to a wall or pillar the effect of this species is very pleasing. The bright orange-yellow flowers are freely produced, usually commencing about July and August, and the plants often remaining in bloom till late in October. Propagation is easily effected by cuttings in the spring. It is a gross feeder, and requires plenty of room to develop its roots. It will grow and flourish in practically any soil, though a good mixture of loam, peat, and sand suits it best. During the summer liquid manure may be liberally applied. After flowering the plants should be pruned hard back to encourage the production of new growths, as the old ones do not flower well a second time.—C. H. MIDDLETON, Kew.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

BEAUTIFUL TREES AND SHRUBS.—R. H. J., Cheltenham: A very handy little book on this subject, well illustrated, and not too large for one's pocket, is "The Book of Shrubs," by Mr. G. Gordon, V.M.H., (2s. 6d., John Lane, Bodley Head.)

PELARGONIUM LEAVES.—A. E. M., Carisbrooke: The weed killer would quite account for the trouble. An overdose of the fertiliser would not act in the same way; it would, as in the case of an overdose of guano, kill the roots, and cause collapse.

SMALL GARDENING DICTIONARY.—G. C., Sutton-in-Ashfield: The best work of the character you desire is Mr. Sanders' "Encyclopædia of Gardening," which may be obtained, post free, for 3s. 10d., from Messrs. W. H. and L. Collingridge, 148, 149, Aldersgate Street, E.C.

SULPHIDE OF POTASSIUM.—F. B., Exeter: It is probably not yet fully understood that sulphide of potassium deteriorates when exposed to the air. It should always be kept in an air-tight vessel when stored; glass jars or bottles, well corked, make suitable receptacles.

YELLOW SWEET PEAS.—S. J. S., Buckingham: There are not any really yellow sweet peas, but there are several varieties with a yellow shade of colouring, and the chief of these are Mrs. Collier, Hon. Mrs. E. Kenyon, Dora Breadmore, Clara Curtis, Primrose Waved, Burpee's Primrose Spencer, and James Grieve. How far these last four differ from each other we are not prepared to say at present.

MAGNOLIA GRANDIFLORA.—T. G., Parkstone: The branches that are extending beyond the limits assigned them should be cut back close to where they start from a stout stem. Do not cut or trim the branches level with the height of the wall, but cut out the smaller extending branches as suggested, and bend down and tie in a few others so that no gaps appear. The work should be done at once.

QUASSIA MIXTURE.—N. E. G., Wycombe: Immerse one pound of quassia chips in three or four gallons of water for twenty-four hours; then remove them, and boil them for an hour in as much water as can be conveniently used. Meanwhile dissolve one pound of soft soap in boiling water. Add the dissolved soft soap to the strained extract from the boiled chips, and to the water in which the chips were previously soaked. Add sufficient clear water to make up ten gallons of mixture

STOVE FERNS.—K. D., Kidderminster: The newer nephrolepis, N. Whitmani, N. Piersoni, and N. todeaoides are extremely beautiful stove ferns, and grow to a large size. A few others of attractive character are Davallia fijiensis, D. dissecta, D. polyantha, Adiantum æthiopicum, A. amabile, A. cardiochlæna, A. Farleyense, A. macrophyllum, A. Lathomi, Asplenium longissimum (for baskets), Goniophlebium subauriculatum (baskets), Phlebodium aureum, Platycerium grande, Lygodium dichotomum (climber), and most of the gymnogrammas, notably G. schizophylla gloriosa.

PEACH TREES ON WALLS.—W. H., Tenterden: The work should be done at once because the flower buds will soon be swelling up, and if pruning and training is left until then there is a real danger of these buds being broken off or damaged. Further, the rising sap is being wasted if it invigorates those shoots that have to be removed. Then also cleaning is best done while the trees are quite dormant; indeed, there is so much work to be done now in the garden that all pruning, training, and cleaning should have been accomplished before this date, so as to leave one free for the business of the moment.

GOOSEBERRIES.—Machany: Excellent varieties of gooseberries for market purposes are Whinham's Industry, Keepsake, Crown Bob, Whitesmith, and Lancashire Lad. Smaller, but of good flavour is Early Sulphur, while for dessert purposes Langley Gage is hard to beat. The quantity of plants needed per acre depends entirely upon the size of the plants purchased and whether the land is to be devoted solely to gooseberries. Planted two feet apart each way, allowing room around the sides, about 10,000 plants will be needed per imperial acre. If there is more land to be filled subsequently, it is a rather good plan to secure two-year-old plants, and place them thus closely together, removing alternate plants the following season and alternate rows the subsequent season, so as to eventually leave the plants four feet apart. We incline to the practice of placing the two-year-old plants three feet apart each way, or about 4,840 per acre, and plant lettuces, or sow turnips, spinach, dwarf beans, beet, or other low-growing and quickly-maturing crop between the rows for the first year or two. Such intercropping keeps the ground well worked and clear of weeds. Two-year-old gooseberries can be purchased true to name at 3s. per dozen, and probably very much cheaper than this in quantity. Your best plan would be to advertise in our columns for tenders for the quantities you need.

NAMES OF PLANTS.

E. H., Taunton.—Cyclamen coum.

S. W. B., Lincoln.—We feel quite sure, from the description, that your plant is Agave americana variegata.

L. A. C., Bath.—1, Abutilon Thomsoni; 2, Asparagus Sprengeri; 3, Phrynium variegatum; 4, Saintpaulia ionantha.

N. F., Guildford.—1, Symphoricarpus racemosus; 2, Helleborus orientalis; 3, Hamamelis arborea; 4, Gaultheria procumbens.

G. S. L., Northampton.—1, Thuia gigantea; 2, Cupressus Lawsonianus; 3, Cedrus atlantica; 4, Cestrum elegans; 5, Moschosma riparium; 6, not sufficient for identification.

Index to Volume of the Gardeners' Magazine," 1907.—Those of our readers who have preserved the 52 numbers of the GARDENERS' MAGAZINE for 1907 with a view to having them bound for future reference, can obtain Handsome Cloth Binding Cases from the publishers, 148 and 149, Aldersgate Street, London, price 2s. post free. The index with title page may be had —price 2d., or by post 2½d., and the volume bound complete, price 12s. 6d., by post, 13s. 4d.

Guides to Garden Work.—The publishers of the GARDENERS' MAGAZINE will be pleased to forward a catalogue of their gardening books, setting out full particulars of the contents of each work. The books, which are thoroughly practical, up-to-date and well bound, will be of particular service to those interested in flowers, the greenhouse, or the garden. A copy of the catalogue will be sent post free to any reader who addresses a postcard to the Publishers, THE GARDENERS' MAGAZINE, 14 and 14 Aldersgate Street, London.

GARDENING AND GARDENERS.

The "hot and cold" effusion from the correspondent who signs himself "A Gardener" in your last issue (p. 97) makes strange reading—strange, at least, to the professional gardener. Your correspondent evidently dislikes those who have not been trained as gardeners being dubbed and treated as "labourers," "interlopers," and "outsiders" by the professional. I really wonder if your correspondent is "a gardener" at all in the proper sense of the term, or whether he is one who fears that he would be "driven from the ranks of the profession" if he were to submit himself to a test imposed by qualified gardeners. It is quite as easy a matter for qualified gardeners to pick out those who know or do not know the business, as it is for a doctor, lawyer, bricklayer, or carpenter to tell the trained man from the "quack." The British Gardeners' Association has been established for this particular purpose in the gardening profession, and it is a pity it was not established half a century ago. If such had been the case, the profession would not have been degraded below the level of the ordinary unskilled labourer—as it too often is at the present time.

Your correspondent evidently thinks the gardener ought still to continue to allow himself to be injured by unscrupulous people. He considers that the gardener who endeavours to protect himself, and to obtain a fair remuneration for the many years spent in learning his business is not only "selfish," but also "foolish." He does not say what adjectives he would apply to the "interloper" who has not spent a farthing or an hour in learning gardening or any other business, but who calls himself a gardener. Such an interloper will work for any wage and spoil the prospects of the real gardener. There are plenty such in the gardening ranks at the present day, and they know absolutely nothing in regard to the culture of fruits, flowers, or vegetables. If these men want to go "back to the land," by all means let them go, but not at the expense of men who know what "back to the land" really means in these days.

I should say that the man who pretended to be a gardener when he knew he was not was nothing short of being an imposter and dishonest—an imposter because he wilfully deceives innocent employers, and dishonest because he does not scruple to take money that he has not honestly earned. Your correspondent, I have no doubt, would think these harsh terms, but, if so, he had better give up his present position of "gardener," and let one of these interloping individuals take his place.

Until the gardener takes a greater pride in his profession, and makes a stronger effort to uphold its dignity, he may be perfectly sure that untrained men will continue to "play the cuckoo" with him. The only chance for the professional is to join the B.G.A., and help to make it into a great national organisation of trained gardeners.

J. Weathers, Secretary, B.G.A.

Those correspondents who have criticised my article in the Gardeners' Magazine appear to have missed the essential point of my suggestions as to the method by which the gardener's lot may be improved. Although I attached great importance to education, I suggested that, without unity of purpose, little would be accomplished, and it is in this direction that the B.G.A. offers great opportunities. I also suggested that, in grading the workers, mere ability to pass examinations should stand for little unless backed by experience, and a combination of experience and ability is what gardeners should endeavour to attain.

Your correspondents agree with me as to the advantage of education, and need for improvement, but they differ as to whether unity, education, and the consequent grading of workers would effect the financial improvement that we desire, but whatever the result only good could possibly accrue from the exertions of young men in the direction that I have suggested, and I maintain that a decided improvement of conditions can and will be achieved through the medium of unity and education, for a combination of these will surmount almost any obstacle.

An examination on the lines suggested by your correspondent "L. B.," in order to be more fair to older men, might easily be arranged if so desired; in fact, a very similar test is arranged by the Board of Education for candidates who desire to obtain a pass in the honours stage for horticulture. But we must break away from the sentimental idea that any change will be unjust to older men in the profession, for the process need not be revolutionary. In the main it would be very gradual, and the only men who would have any cause for complaint are those who are at present content to drift through life (as a jelly fish drifts through the sea), with the least possible trouble or exertion on their own part, and it is my desire to arouse in these some recognition of their responsibility.

A. G. B.

Feeding Hyacinths in Glasses.—The consequences of feeding hyacinths growing in vases of water are generally so disastrous that it is much better to leave well alone, and not feed. Chemical manures are so highly concentrated that the merest pinch in a hyacinth glass is likely to cause trouble, and I have never yet met the cultivator who could give pinches small enough to do good, and not harm. If plenty of rain water and a little charcoal are forthcoming, there is no need to attempt feeding with artificials.—E.

GEO. COOLING & SONS'
STRONGLY RECOMMEND THE
New Giant Lily of the Valley.

Fortin's New Large-flowered Lily of the Valley is quite distinct. Being twice the size and substance of the ordinary variety, it produces long, stiff stems and flower-spikes averaging one foot in length, the individual bells being of immense size, and often 18 to 20 on a spike. For pot culture it is unsurpassed, and it will thrive in any ordinary soil out of doors. A most valuable acquisition, which should be found a place in every garden. Strong flowering crowns, per doz., 2s. 6d.; per 100, 15s., post free.

COOLING'S NEW SEED CATALOGUE contains a full list of choice Bulbs and Roots selected for spring planting, forwarded gratis and post free.

THE GARDENERS' MAGAZINE.

NOTES OF THE WEEK.

Winter Growth.

When we consider that warmth and light are recognised as the chief factors in plant growth, and that at the approach of winter as the flood of sunshine wanes and the temperature consequently falls the greater part of vegetation falls asleep as it were, it is somewhat of a puzzle that other plants seize upon that very time to waken up and grow actively in preparation for early spring-flowering; some, indeed, like the hellebores and the winter aconite actually flowering in the depth of winter. We see this phenomenon in all our spring flowering bulbs, tulips, hyacinths, daffodils, scillas, and all their kin. Roughly speaking all these may be said to remain perfectly dormant and impervious to all the vivifying influences of summer sun and shower, and only to wake up and start growth about November. It is, however, mainly the root system which acts thus, and in some cases, daffodils for instance, we shall find undisturbed bulbs showing visible root development even as early as August, a curious fact when we remember that the leaves will not push until fully six months later, so that it is somewhat difficult to understand what office the roots can perform for the major part of the time, especially in the case of good plump bulbs in which are already compactly stored the future foliage and flower. It is probable that the roots of many other plants are more or less active in the presumed dormant season. Ferns, for instance, may give evident signs of awakening long before a definite upward rise of the fronds occurs, the crowns swell and fatten as it were as a preparatory step, and this, of course, is an indication that the roots are busy. Such plants, too, as roses, clematis, aucubas and other shrubs, which seize upon every mild spell in the winter to push out their buds and shoots in a most improvident fashion, can also only do so by virtue of root energy, which in exotic plants is due to inheritance of tendencies less fitted for our climate than for their native ones. In this connection it is curious how difficult or even impossible it appears for some imported plants to accommodate themselves to the altered climate. Thus we see the rosy-pink blossoms of the almond open persistently at a time of year which is almost invariably incompatible with fruit-producing fertilisation, while our native trees on the other hand, persistently resist the blandishments of sunny winter or even spring days, and keep their buds tightly closed until they are fairly safe from nipping frosts. Even in these cases, however, it is probable that the root systems are at work long before the period when the buds shown signs of bursting; there is most likely a slow accretion of vital force and of sap within the system of the plant, in preparation for the wonderful activity which is evinced when we see the thousands and tens of thousands of buds on a large tree all simultaneously breaking out into bunches of leaves and probably of catkins and flower buds in addition. The work to be done by the roots at this period must be enormous, and judging by what we note in other plants, it is hardly likely that during the winter, in the protected and warmer depths of the soil, no reserve of force is being laid up for the coming task. That we see no evidence of root vigour in the shape of leafy excrescence during the so-called dead season, is no proof that the root system is entirely dormant. If we consider a large tree with its broad, naked expanse of trunk, branches, and twigs exposed to a dry north-easter in midwinter, we must assume that the drain set up by evaporation must be neutralised by true movements of sap, for if we severed a branch and exposed it to such conditions for any length of time it would be perfectly dry and killed, a proof that the roots must still be active and prepared for such a call upon their resources.

MR. H. B. MAY.
Chairman of the Committee of the Royal Gardeners' Orphan Fund, and of R.H.S. Narcissus and Tulip Committee.

Mr. H. B. May, whose portrait we have much pleasure in giving in this issue, is well-known to those engaged in commercial horticulture as one of the leading exponents of the difficult art of market culture; and in horticultural circles he is recognised as possessing administrative abilities of an exceptionally high order. For many years past Mr. May has been a member of the Council of the Royal Horticultural Society, and notwithstanding the exacting requirements of a large and highly successful business he has been so unremitting in his attention to the duties of his office as to be held in the highest estimation by his colleagues; not only has he been a member of Council, but he has for a number of years been the chairman of the society's Narcissus and Tulip Committee, and a vice-chairman of the Floral Committee, and in both of these positions he has by reason of his ability and tact won golden opinions from the members of these two bodies. In addition to the offices he holds in connection with the Royal Horticultural Society, Mr. May is the chairman of the Royal Gardeners' Orphan Fund, a position he has occupied since the retirement of Mr. William Marshall, V.M.H., many years ago; and it may be added with singular advantage to the charity. The high estimation in which Mr. May is held by his colleagues was exemplified by his unanimous re-election at the meeting of the committee on Wednesday last. Mr. May has, in the conduct of his extensive market growing establishment at Edmonton, been exceptionally successful with the several classes of subjects that he has taken in hand. He has, perhaps, devoted more attention to the nursery side of market culture than is customary, and he has shown rare judgment in seizing on good things and then developing them in such manner as to prove to demonstration their value. The beautiful Campanula Mayi, and the finest of the crotons and ixoras may be mentioned as examples. Mr. May is also an extensive grower of exotic ferns, as exemplified by the comprehensive and finely grown collections exhibited at Westminster, and he has raised a considerable number of new varieties of these elegant plants. Of late years much attention has at Edmonton been devoted to British ferns, which we are pleased to know are beginning to receive the attention they so well merit. Some two or three years since Mr. May's two sons were taken into partnership, and were it within the province of this note to speak of them, it would be our pleasant duty to say that they are following closely in the footsteps of their father. Higher praise it would be difficult to give.

The "Gardeners' Magazine" Spring Number will be published on March 7, and the arrangements that we have made are such as to enable us to suggest that it will be the most interesting and attractive of the issues specially associated with the spring season we have yet published. The contents will include "Some Famous Cornish Gardens," "Deciduous Calanthes," "Sweet Peas for Exhibition," "A Garden of Annuals," "Recent Advances with Lilacs," "Advantages of Winter Spraying," "Weeping Standard Roses," "Long Keeping Apples," "Garden Seats," "Pyramidal Ivy-Leaf Pelargoniums in the Flower Garden," "The Care of Garden Tools," "Moon Daisies," and "Winter-flowering Carnations for Private Gardens." The spring number will be profusely illustrated, and in addition a plate in colours of early-flowering tulips will be presented with every copy. As we anticipate a large demand, we would suggest that those of our readers who require extra copies should give their orders well in advance of the date of publication.

Acreage of Hardy Fruits in Great Britain.—The increasing importance of fruit culture in Great Britain has given rise to a demand for more detailed statistics than have hitherto been collected by the Board of Agriculture. The returns annually obtained of the total area under orchards and small fruits have afforded a rough measure of the growth of the industry as a whole, and show an increase during the past ten years of 25,000 acres of orchards, and 12,000 acres of small fruits. In 1907 an endeavour was made by the board to obtain more detailed returns, while at the same time maintaining the continuity of the statistics. Occupiers were asked to return the small fruits under four, and orchards under five, headings, and as there has been a ready response to the request the returns are of greater value and interest than in previous years. The returns show that in 1907 there were in Great Britain 27,827 acres of strawberries, 8,878 acres of raspberries, 25,590 acres of currants and gooseberries, and 19,880 acres of other kinds, making a total of 82,175 acres of small fruits. The areas under orchard fruits was as follows: 173,643 acres of apples, 8,911 acres of pears, 12,027 acres of cherries, 14,901 acres of plums, and 41,694 acres of other kinds, total of orchard fruits, 250,176 acres. Adding the two totals and deducting the 23,492 acres of small fruits in orchards, the area under fruits of all kinds was 308,859 acres. As compared with 1906 there was an increase of 2,489 acres under orchards and an increase of 1,949 acres under small fruits.

Royal Horticultural Society.—At the general meeting on Tuesday, March 3, Mr. E. White will lecture on "Bulbous Plants of New Zealand," the chair as usual to be taken at 3 p.m. On March 5 and 6 the society will hold an exhibition of Colonial grown fruit and vegetables, both fresh and preserved. As a matter of considerable interest, it may be mentioned that 96 new Fellows were elected at the annual meeting on the 11th inst., making a total of 192 since the beginning of the present year.

Gardening Books at Croydon.—The Croydon Public Libraries Committee, recognising the importance of keeping the residents within the borough fully informed as to the books under their charge, hold from time to time exhibitions of books, drawings, etc., relating to the different trades and professions. On Saturday, the 15th inst., they held an exhibition of books on gardening and allied subjects, which was of much interest, as indicating the fine collection of horticultural works in the Croydon Library. The books were arranged on three tables in the lecture room, which was open to the public, and many gardeners and others interested in gardening visited the exhibition during the afternoon and evening. To still further increase the usefulness of this section of the library, the chief librarian sends to each meeting of the Croydon Gardeners' Society a selection of books that relate to the subject of the evening, and the members of the society can obtain one or two volumes on loan till the following meeting, or they can exchange the books at the library for others during the interval. A library talk on "The Old Gardens of Croydon," illustrated by lantern slides, will be given at the library by Mr. John Gregory on April 7.

English and Italian Gardens.—A few evenings since Mr. T. H. Mawson read a highly interesting paper on "English and Italian Garden Architecture" before the members of the Leeds and Yorkshire Architectural Society. In Mr. Mawson's opinion that, as illustrating the art and science of landscape gardening, French and Italian examples were superior to the English; but for mere lovable beauty, nothing could approach the English garden. The charm of an English garden was the refreshing carpet of green grass. In the Italian garden there was no such keynote, but the reverse. This was necessarily so, because after the fierce sun of June only a few extreme sun-delighting flowers, such as pelargoniums or a few subtropical flowers continued to bloom throughout the remaining hot months, and these flourished best where they could gain a welcome shadow from a friendly wall or hedge, and so an abundance of adornment in the shape of walls, balustrades, fountains became a necessity, and supplied the interest that grass and flowers yielded in our home gardens.

Gardeners' Royal Benevolent Institution.—Under the will of the late Mrs. Rylands, of Manchester, this institution has received a legacy of £3,000.

National Chrysanthemum Society.—The fourth annual dinner of the members of the society and friends who are specially interested in the market show will dine together, under the presidency of Mr. R. Ballantine, at Lyons' Popular Café on Monday next, the 24th inst., at 7 p.m. Tickets (price 4s.) may be had from the secretary, Mr. R. A. Witty, St. James's Villa, Swain's Lane, Highgate, N.

Water for London Gardens.—At the meeting of the Metropolitan Water Board, held on the 14th inst., a report on the supply of water to gardens was brought up by the Appeal and Assessment Committee and discussed at some length. The committee recommended that where the rateable value of the premises exceeds £200, or a sprinkler is used, the water for the garden should be separately supplied by meter at the trade rate, but without imposing a minimum rent; and for gardens where the rateable value is less than £200, the following should be the scale of charges for the season: Not exceeding £50, ten shillings; not exceeding £100, fifteen shillings; and not exceeding £200, twenty shillings. The recommendations of the committee were adopted.

An Examination in Elementary Horticulture for lads and young men under 19 years of age will be held under the auspices of the Royal Horticultural Society on Wednesday, March 25, in as many different centres in Great Britain and Ireland as circumstances may demand. The general conduct of this examination will be on similar lines to that of the more general examination. Intending candidates should write at once for a copy of the syllabus to the secretary, Royal Horticultural Society, Vincent Square, London, S.W.

Smethwick Horticultural Society.—As the outcome of a small flower show held last year in the West Smethwick Park, a horticultural society has been formed at Smethwick with Mr. G. F. Chance as president, Dr. Broughton as treasurer, and Mr. J. D. Bexon as secretary.

Ruffled Gladioli are among the most recent plant novelties that have originated in the United States. The ruffling does not, we need harly say, refer to a disturbance of the feelings of the plant, but to the frilling of the margins of the segments of the flowers. This frilling or ruffling is not very pronounced, judging from the illustrations that have come under our notice, but the raiser is said to have other varieties in which this characteristic is more highly developed.

British Gardeners' Association.—A public meeting will be held by the Richmond and District Branch of this association in the Wesleyan Schoolroom, Evelyn Road, Kew Road, Richmond (nearly opposite the County School), on Tuesday, February 25, 1908, at 8 p.m. An address will be given by Mr. J. Weathers, secretary of the association, supported by other members of the executive council. The chair will be taken by Mr. E. F. Hawes, treasurer of the association.

Exhibitions and Meetings at Regent's Park.—The Council of the Royal Botanic Society have made the following arrangements for exhibitions and meetings during the current year. Monthly flower shows, Wednesdays, March 25, April 22, May 20, and October 7. The Great Horticultural Exhibition, Wednesday, Thursday, and Friday, June 17, 18, and 19. The National Rose Society's Metropolitan Rose Show, Friday, July 3. Messrs. Waterer's annual exhibition of rhododendrons at the beginning of June. Afternoon musical promenades, Wednesdays, June 24 to July 29, 3.30 to 6 o'clock; and illuminated evening fêtes on the evenings of the same days, from 8 to 11 o'clock. Wednesday, July 15, the Women's Agricultural and Horticultural International Union will hold their annual exhibition of produce. An exhibition of the society's collection of chrysanthemums during November in the conservatory and corridor. Fellow's meetings for the election of new subscribers, scientific discussions, etc., on the fourth Fridays in the month, at 4.15 p.m. from November to March, and at 4.45 p.m. from April to July. Anniversary meeting will be held on Monday, August 10, at one o'clock.

Cure for the Orange Fly in Tasmania.—In many countries where oranges are largely grown serious damage is often done to crops by the Orange Fly (Ceratitis capitata), a pest that also infests peaches, apricots, and even apples, pears, and plums. It has recently been found that the flies are attracted in a most powerful manner by kerosene, and when the latter is placed in shallow vessels among the branches of the trees, especially in dry weather, the flies enter it and are killed. We understand that the orange fly has made its appearance in the neighbourhood of Paris upon peaches; we therefore urge growers of peaches, etc., who are resident in the south-eastern counties to keep a sharp look-out for any new insect that may appear.

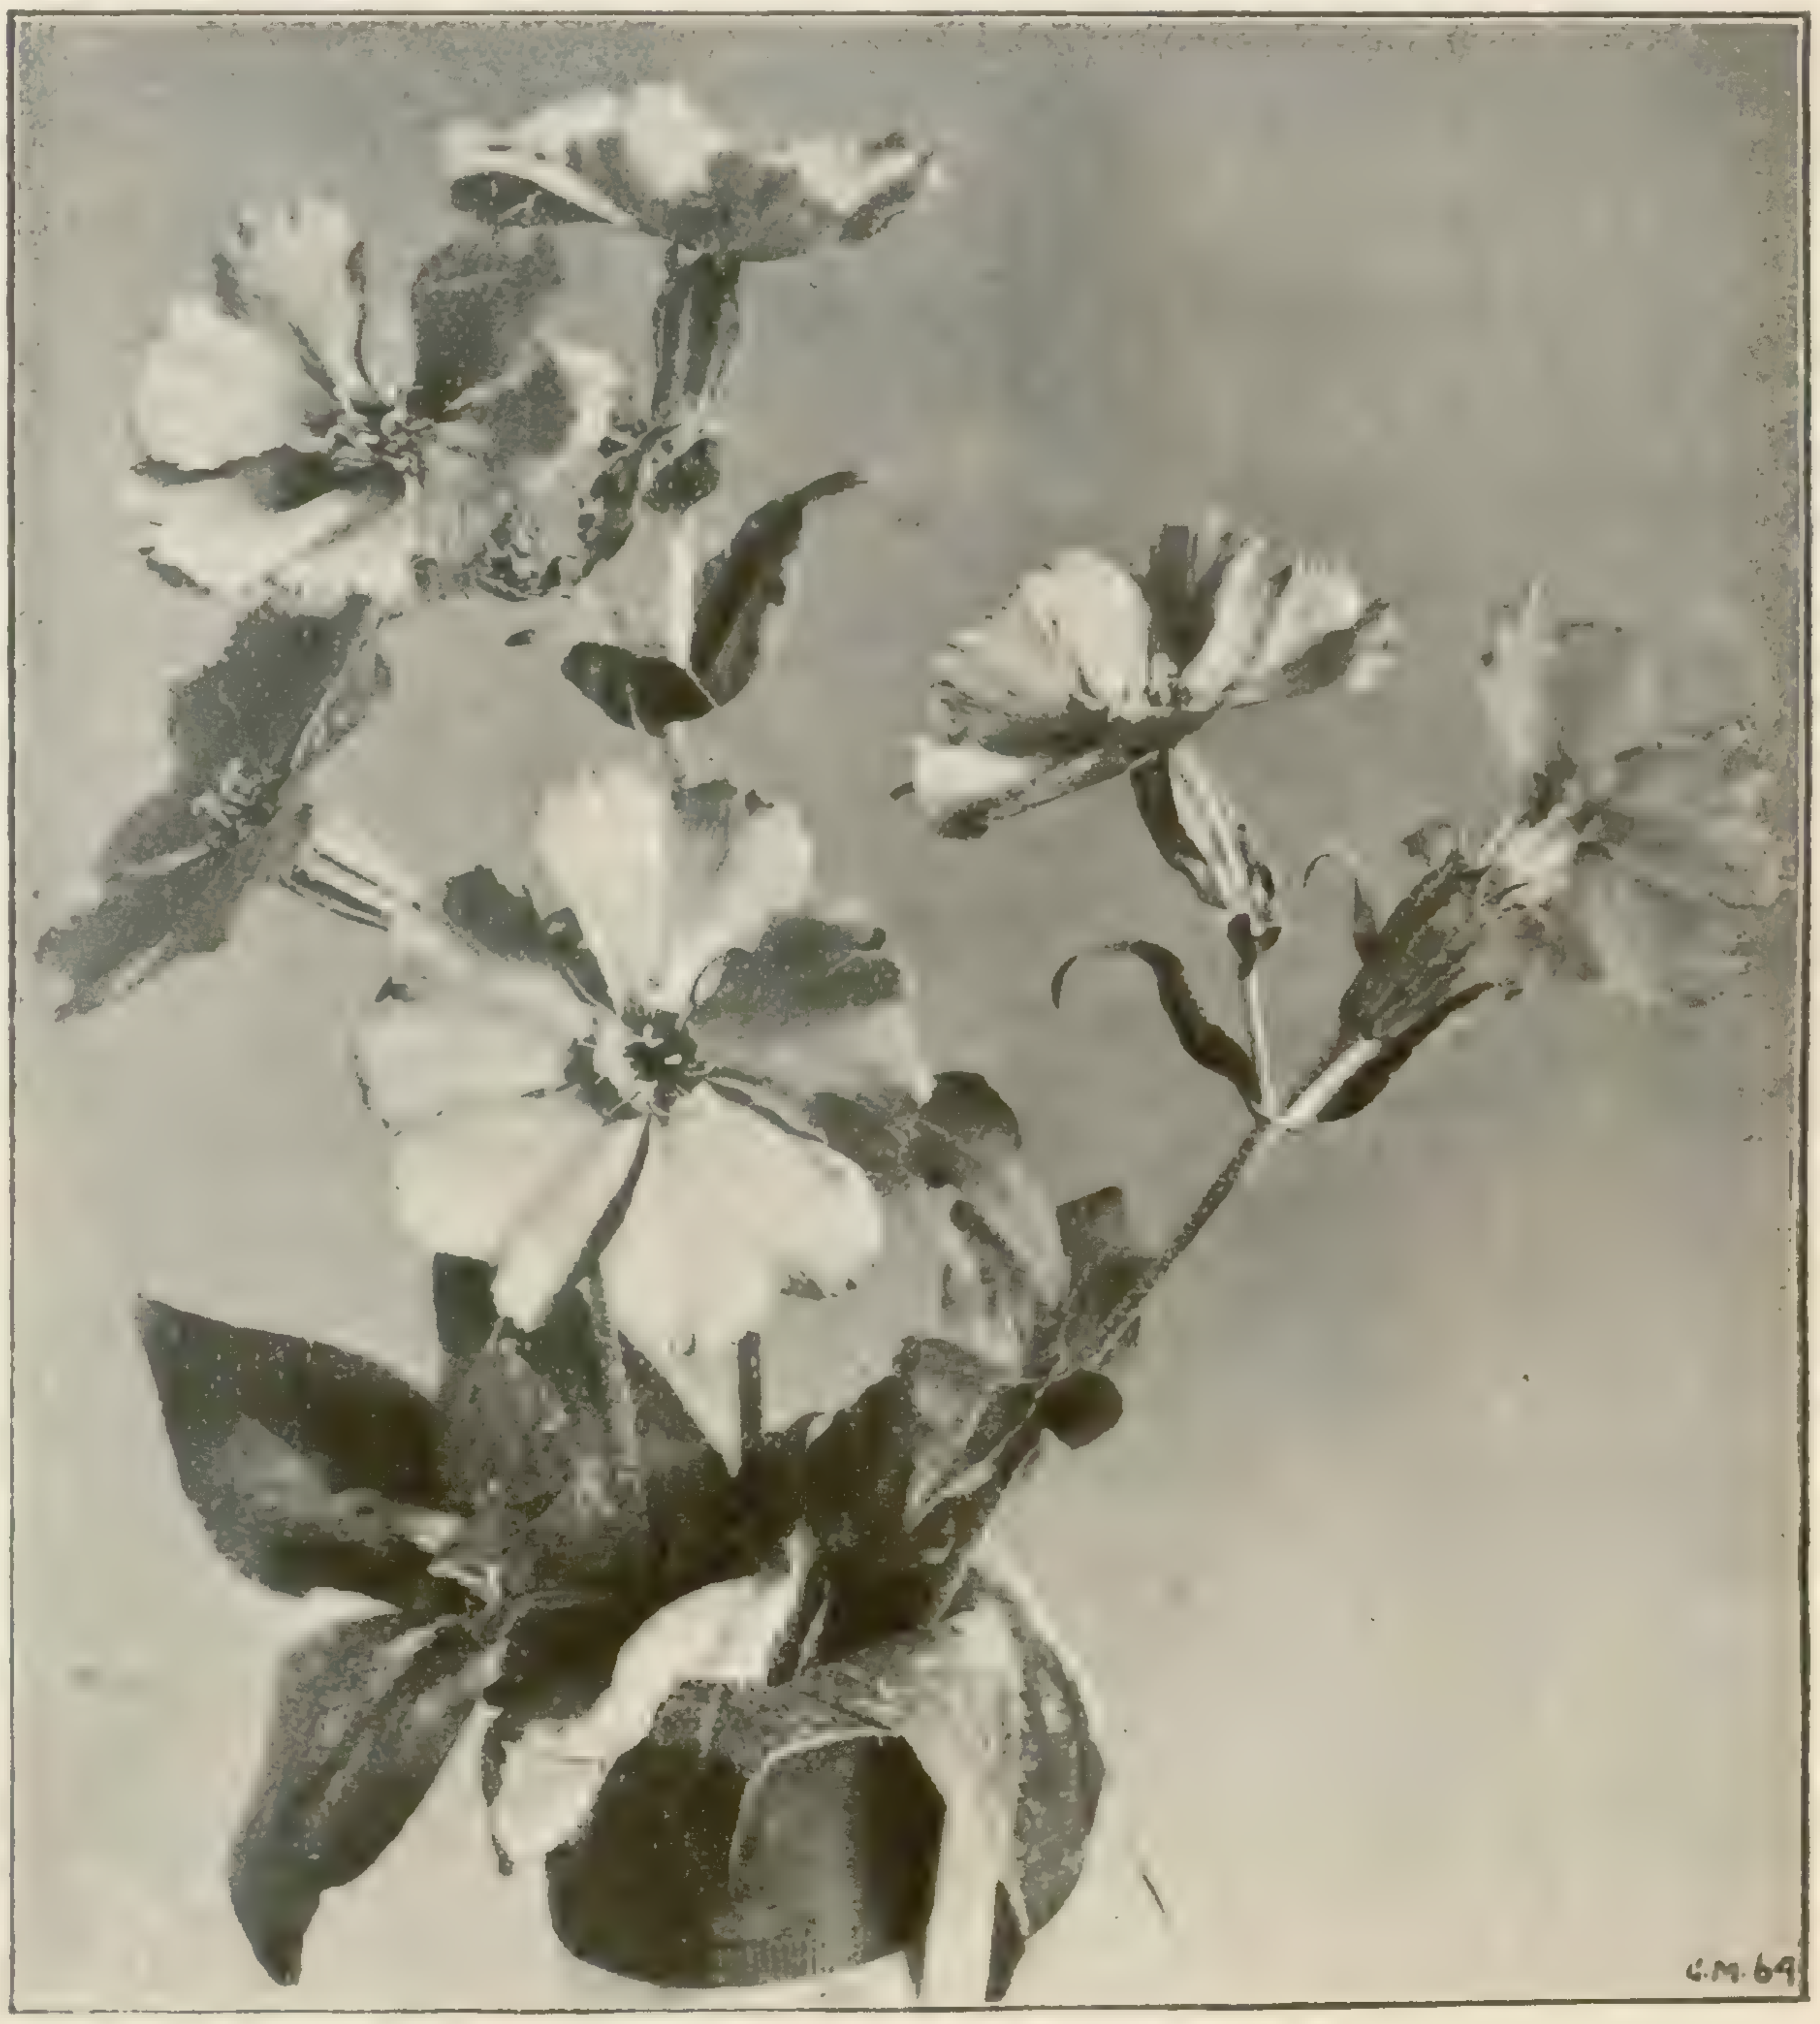
National Rose Society.—The following are the dates of the exhibitions, committee meetings, and annual dinner arranged for the current year: Metropolitan Show at Royal Botanic Gardens, Regent's Park, Friday, July 3; Provincial Show at Manchester, Tuesday, July 21; Royal Horticultural Hall, Thursday, September 17; annual meeting, at 3.30 p.m., and annual dinner, at 6 p.m., December 10; general committee meetings, March 3, April 14, May 12, June 9, October 13, November 10, at 3 p.m.

The Value of Cross Fertilisation as a means of infusing greater vigour into the constitution of various races of plants has been brought into prominence in the course of the experiments that have been made in the United States in the raising of Lilium Harrisi from seed. In California the best success has, it is stated, been obtained with seedlings which were obtained by crossing the red-stemmed Lilium longiflorum giganteum with Lilium longiflorum Harrisi. The progeny is remarkably strong and in some localities totally free from disease. One grower bloomed a large number of seedlings in the spring of 1907. Although the seedlings were only about three inches high when planted out in June, 1906, some of them had twenty-eight flowers to a single stem in June, 1907. Two years ago another grower had some two-year-old seedlings of the same cross, one of which had thirty-five flowers to a stalk. In one case the grower had during May, 1907, hundreds of plants with twenty or more flowers to a stem.

LYCHNIS GRANDIFLORA.

Lychnises, as a whole, are among the brightest and most effective border flowers, and their value to the majority of gardeners is greatly increased by the form of the flowers, which give an excellent contrast to the almost superabundance of composite plants in the garden late in summer and autumn. As everyone knows, the colours of many are of the brightest imaginable hues, and looking at some of these one can well understand why the name has been applied to these plants, originating, it is said, from the flame-like colouring of the blossoms.

Many of these lychnises have been in British gardens from time immemorial, but there is still room for more good species or varieties, and thus a hearty welcome awaits a really good and distinct one when it becomes available.



LYCHNIS GRANDIFLORA.
Flowers rose-salmon suffused with crimson.

Such a welcome awaits the beautiful and showy Lychnis grandiflora, which is here figured, and which was exhibited by Mr. Amos Perry at the meeting of the Royal Horticultural Society on September 3 last, when its merits received due recognition by the Award of Merit made by the Floral Committee. Although not a new plant, it has not been generally in commerce, and appreciation awaits it from the many hardy flower lovers who read this journal. Its general appearance is well indicated by the illustration, but the brush of the painter is required to give an idea of the bright colouring of the flowers, which are about three inches across, and are of a hue variously described as deep salmon, or rosy salmon, with almost a crimson shade. The formation of the flowers is pleasing, and the slight irregularity of the petals is rather a virtue than a defect in the taste of the present time. The height is about two feet, so that the plant is one suited for the small garden as well as the large one.

The cultivation of Lychnis grandiflora presents no great difficulty, but, like others of the race, it is the better for frequent renewal, either from cuttings or seeds, the latter giving more vigorous plants. It likes a border with a fair amount of moisture, and there it will be longer lived than in a dry one.

The nomenclature of these lychnises from China and Japan, whence this species comes, is somewhat involved, and difficult to unravel. L. grandiflora is, however, considered to be a true species, and is given specific rank both in the "Index Kewensis," and in the "Handlist of Herbaceous Plants," issued from our great national establishment at Kew. According to some, L. grandiflora is synonymous with the plant known as L. fulgens grandiflora, which, again, has been held as synonymous with L. Bungeana. This is not in accordance with the authoritative publications already quoted.

It may be added that another lychnis grown by Mr. Perry as L. striata, resembles L. grandiflora, except in the colour of its flowers, which are bright scarlet with white stripes. Both L. grandiflora and L. striata are good garden plants, and the writer's experience with the former, formed from the cultivation of a plant received from a Continental source a few years ago, is of a favourable nature.

S. Arnott.

CALADIUMS.

As ornamental foliage plants to decorate our warm stove houses from April to October caladiums are unequalled, their cordate or sagittate leaves and gorgeous colours rivalling many a flowering plant, and they are even more appreciated by many a plant lover. Visitors to the Temple Shows at the end of May can see them staged to perfection by several well-known firms, who of late years have made a special feature of these plants. As decorative subjects for the dwelling house they need to be gradually hardened as growth matures, or the cold draughts from doors and windows causes them to droop, and then their beauty disappears.

The small silvery Caladium argyrites is a gem for dinner table decoration, for the front row when setting up a group, and for filling baskets or stands within the mansion.

The time is now with us when a part of the stock of caladiums should receive attention, and if growth has not yet commenced they should be watered and stood near the glass in a temperature of 65 degrees by night; here new growths will soon be apparent, and then the corms should be turned out of their pots, divested of all soil, and cleaned, any decaying parts being cut away with the knife, rubbing a little dry flowers of sulphur over the cuts. If it is desirable to increase the stock, cut the tubers into small pieces, making sure that each piece has a crown; very serviceable plants can thus be had in one season, and the variety argyrites lends itself well to this treatment. Use clean pots, well drained, varying in size from four inches to eight inches in diameter. It is best not to put the plants into large pots at once, but rather to transfer the more robust varieties into eight-inch pots when they have filled the smaller size with roots, the former pots being large enough to grow good specimens in.

The usual soil, peat, loam, and leaf-soil, with clean river or silver sand added, that will grow stove plants generally will suit caladiums well. Place the soil in the house where the plants are growing a day or so previous to potting. Rather more than half fill each pot with soil, make it moderately firm with the fingers, add a pinch of sand for the corm to rest on, and then put in sufficient soil to just cover the corm. If a gentle bottom heat can be afforded, such as fresh leaves or tan give out, growth will be accelerated, and a smaller amount of water be necessary until the roots permeate the new soil.

Caladiums stand the sun fairly well, although a very thin shade from early in May onwards for a few hours daily will prove beneficial. As soon as the pots become full of roots weak liquid cow, sheep, or deer manure may with advantage be given twice or thrice a week. Overhead moisture is also good for them, but the syringe must not be used with any degree of force or the leaves will quickly be broken, which means disfigurement for the whole season. Some varieties are prone to throw up flowers at an early stage of growth; such stems should be pulled out as soon as detected. Stand the plants as near the glass roof as possible, so that all the light can reach them, and as many produce massive leaves a thin stake must be provided betimes, care being taken that these are not stuck into the corm.

There are numerous varieties, all more or less beautiful, so there is no need to particularise. A visit should be paid about midsummer to any nurseryman who makes a speciality of them, and selections made when they are in their full glory. Many tubers are lost through the winter, either through being kept too dry or too wet, and in some instances in too low a temperature; but where the thermometer does not recede below 55 degrees or advance much above 70 degrees, and a happy medium is maintained as regards moisture in the soil, losses will be very small. Lightly fumigate if aphis obtains a footing, and sponge the leaves carefully if mealy bug puts in an appearance. J. Mayne.

Bicton Gardens, Devon.

EARLY CUCUMBERS.

At this time of the year cucumbers are rather difficult to obtain, old plants may be encouraged to make a little fresh growth by giving some good rich soil mixed with horse manure and applied as a top-dressing. With this assistance they will perhaps give a few fruits till the earliest plants raised from seed sown some weeks ago are ready for planting or bearing. This very often means getting rid of the old stock to ensure a clean house, that is, suitable for raising early cucumbers. The house for receiving early plants should be thoroughly cleaned, the walls and pipes sealed with hot water, the walls whitewashed and the pipes painted, if possible, to get rid of red spider and other insects.

Then proceed to put in fermenting materials consisting of half stable manure and fresh leaves for bottom heat. The hotbed is desirable, even if there is artificial bottom heat underneath. Keep the bed well up to the glass, treading it down firmly.

Cover the surface with a layer of fresh cut turf grass side downwards, and proceed to prepare the mixture for the bed. A suitable compost may be formed with turfy loam cut up from a pasture, and some old spent mushroom bed added to it. In breaking up the loam all wireworm should be picked out. When the soil is warm enough to receive the plants and the bed is well settled down, they may be at once planted, taking care not to break the ball of soil.

Where the old stock cannot be spared and the room is limited, three or four plants, or as many as can be found room for may be shifted on into 10 or 11 inch pots, and placed in a warm house suitable to give a few early fruits. These like plenty of heat and moisture; a temperature of about 70 degrees at night, and up to 80 degrees by day, will be the most suitable. They must not have much air or mildew will occur. Keep the paths, wall, and other things in the house well damped over. Where there is no propagating pit the early cucumber house is a splendid place for raising all seeds.

Paddockhurst. A. B. Wadds.

Dividing Rhubarb Clumps.—This is work that should be undertaken as soon as the state of the ground enables it to be done under comparatively pleasant conditions. Only a portion of the plantation should be operated on, as it is not advisable to pull leaves in the first season after dividing. First, a piece of ground should be made ready for the divisions, and, as they will not be disturbed again for several years, it is well to give the ground a thorough preparation by deeply digging it, and placing plenty of fat manure well down below the surface. An axe is a useful tool for dividing real tough old clumps, but a sharp spade will answer for others. The clumps should be divided into single crowns, and these should be trimmed into shape a bit with a knife. The broken roots should also be cut off slantingly, and then the crowns planted so that their noses just protrude above the soil, 2ft. to 3ft. apart.—E. J. K.

THE QUEST OF THE YELLOW SWEET PEA.

Of all the phases of the sweet pea cult the quest of the yellow sweet pea is perhaps the most fascinating, and certainly the most elusive. There is no doubt that the pure yellow sweet pea (when it comes) will bring a golden harvest for the raiser, but at present the "game is anybody's," and there are many enthusiasts who are working assiduously to obtain it.

But as the sweet pea is so sportive in character, and so many notable varieties are certainly sports, the yellow sweet pea may perhaps turn up in an unexpected and unconventional manner, to gladden the heart of some plodding florist who may have never considered the likelihood of such a prize falling to his share.

It was not really long ago that we were praising the Hon. Mrs. E. Kenyon as being the variety which seemed to point the way toward the yellow sweet pea; last season Mrs. Collier was the prime favourite in this shade, and now Eckford's primrose-hued James Grieve provides us with the nearest approach to yellow. It is real progress, certainly, for there is a great difference between the first-named and the last varieties, but for all this we are still a good way off the pure yellow variety.

It may, however, be quite possible for the new cream-coloured and primrose forms of Countess Spencer to break again into sports of a decided yellow hue, for the possibilities of the Spencer group are so well known that no one would be surprised if further advances came from such a source. On the other hand, a series of crosses between these creamy Spencer forms and James Grieve would provide an interesting task for an enthusiast, and perhaps furnish a further improved race of seedlings, some of which might be reasonably expected to surpass their parents. The finest of these seedlings, interbred, using only the very finest for this purpose, should bring the worker another step forward, and well in sight of the yellow sweet pea.

Selection of existing varieties also affords a means of advance, for in the majority of the sweet peas, however perfectly fixed, forms may be met with that are larger in size and richer in colouring than the majority of their fellows, and if these are isolated and the resulting seed saved, a moderate amount of success may be reasonably expected, especially if these finer forms have been carefully hand fertilised.

Although one would advise the inter-crossing of primrose with primrose, or primrose with cream, yet there is a possibility of the yellow sweet pea coming from another source, namely, from those buff, salmon, and apricot shadings which are to be met with in some varieties. These shadings are often the offspring of * yellow flowers, and there is just the possibility that the yellow is lying dormant under one or other of these hues. A series of crosses with white and cream-coloured varieties would probably settle the question, using these same salmon, apricot, and buff shades both as pollen parents and as seed bearers.

In conclusion, we can but rejoice that the "cult of the sweet pea" has become so popular, for besides providing a feast of interest, and a wealth of new colourings which are appreciated by all, it gives a big lift to the horticultural trades in general, and provides attractive exhibits for the summer shows. P. S. Hayward.

---

* Referring to other groups of plants, in which yellows have been noted for their tendency to produce seeds which embrace the shadings spoken of.

WEBBS' GOLD MEDAL PRIMULAS

AWARDED PREMIER HONOURS AT THE LEADING EXHIBITIONS OF THE KINGDOM.

WEBBS' NEW SNOW QUEEN.

Pure white. **2/6** per packet.

"Webbs' Snow Queen is a giant Primula producing very fine trusses of large white flowers."—*The Garden.*

WEBBS' EXQUISITE.

Mixed colours. **2/6** per packet.

"At the Hartlepool Show I gained First Prize with your Exquisite Primula in the Open Class. The strain is splendid."—Mr. G. Waterworth, The Gardens, Meadowcroft.

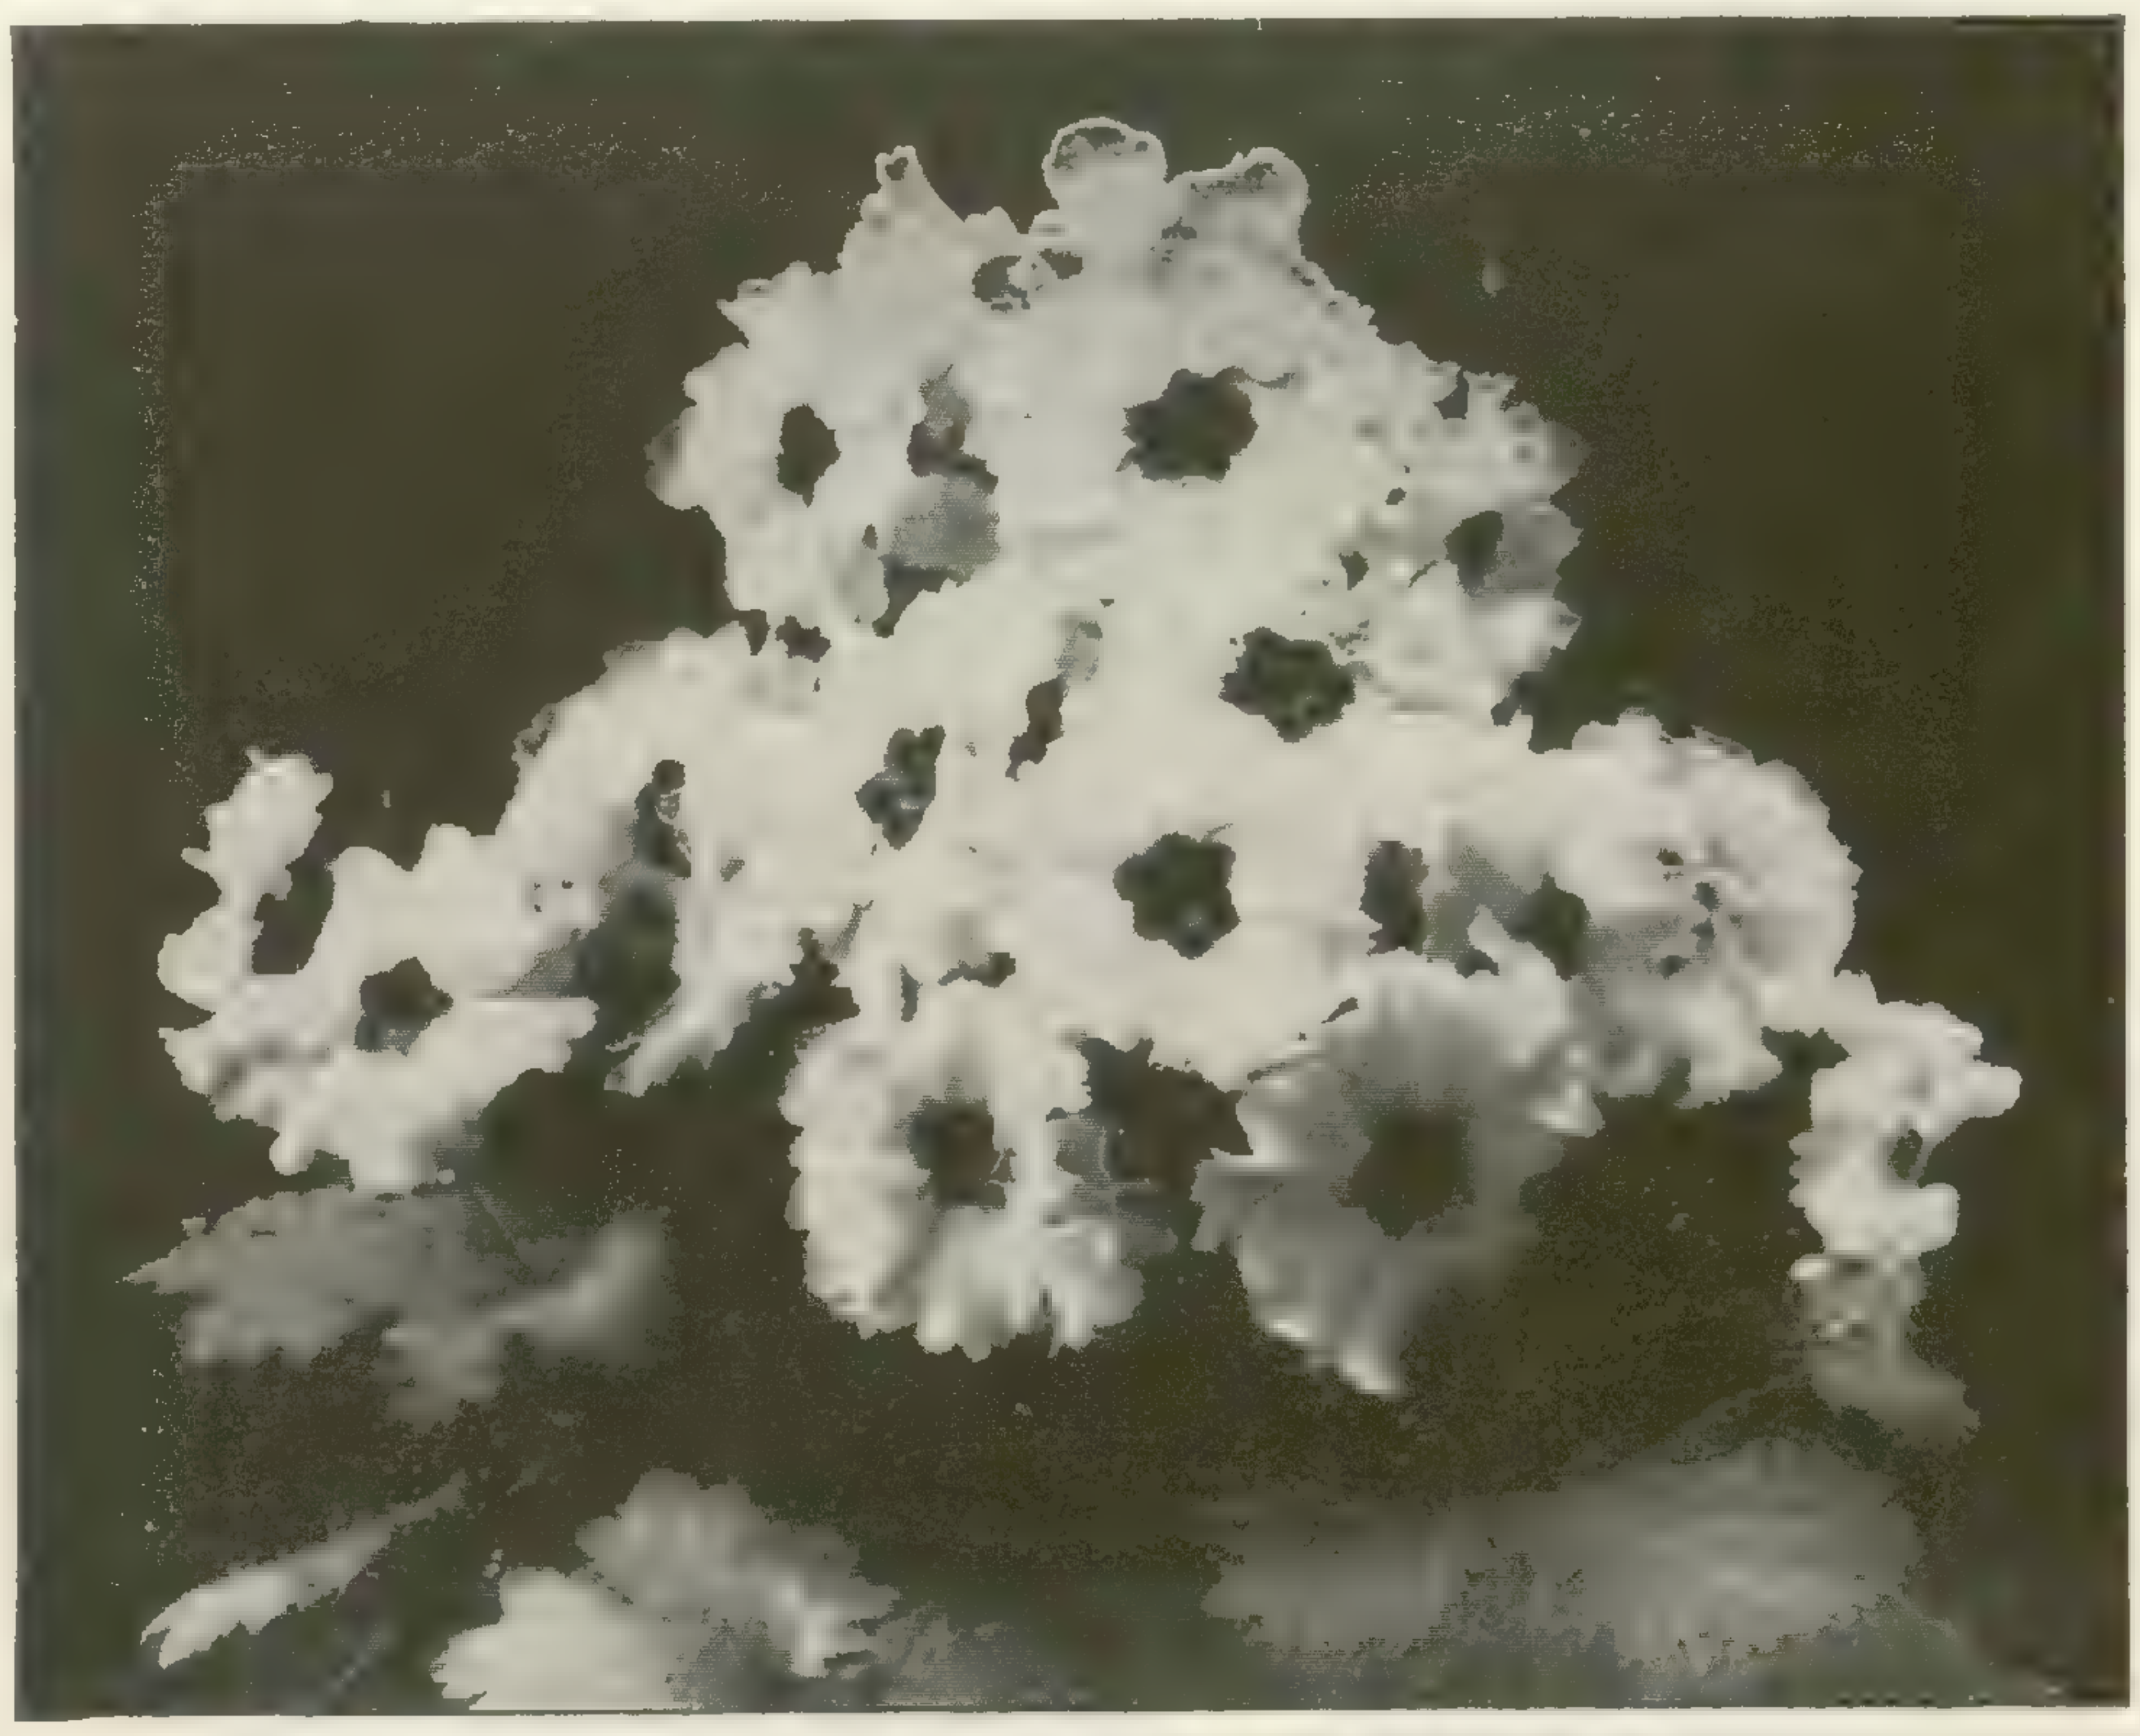
WEBBS' NEW METEOR.

Salmon-rose. **2/6** per packet.

WEBBS' DOUBLE.

Double white, double red, double salmon, and double mixed.

Each ... ... **2/6** per packet.



WEBBS' NEW AVALANCHE.

Pure white, with a greenish-yellow eye. **2/6** and **5/-** per packet.

"I am charmed with Webbs' New Avalanche Primula, and consider it by far the best white Primula that has come under my notice."—Mr. E. Beckett, The Gardens, Aldenham House, Elstree.

WEBBS' NEW RUBY QUEEN.

Rich ruby. **2/6** per packet.

"I took First Prize at Windsor Show with your Primulas, against 10 competitors."—Mr. B. Campbell, Gardener to Her Grace the Duchess of Sutherland.

WEBBS' MODESTY.

Carmine-rose. **2/6** per packet.

"I obtained First Prize with Webbs' Modesty Primula in a strong competition. They were the admiration of all."—Mr. W. Knight, The Gardens, Rodmersham.

WEBBS' BLUE BELLE.

Light blue. **2/6** per packet.

WEBBS' STELLATA.

White, blue, salmon, red, scarlet and mixed colours.

Each ... ... **2/6** per packet.

WEST'S PATENT GARDEN SUNDRIES

Have been invented during 25 years of practical experience in horticultural sundries, that by the better cultivation of plants and the pleasure by which gardens are kept in order their expense is doubly repaid.

ORDER FORM. *(Address here.)*

(To be filled up and handed to your Seedsman to execute for free delivery, thus saving carriage.)

To Messrs.

Kindly supply the following:

Qunty. ***WEST'S PATENT GARDEN SUNDRIES.*** £ s. d.

„ **Rafflatape,** coils better than raffia. 1d. coil ties up 150 plants. 7 coils (100 yds.) for **6d.** ...
„ „ reels, with holder to fasten in buttonhole, 250 yds., complete **1/6** each ... ...
„ **Wall Tree Fasteners,** aluminium. Fastens on and off any nail in a wall, 50 for **1/-** ...
„ **Powder and Spray Syringe,** most useful article, **6/-** each ... ...
„ **Nicofume.** Complete self-contained fumigator, holding ½oz. 95% nicotine, **6d.** ea., **5/9** doz.
„ **W.E.O.N. Insecticide.** Sold under a £20 guarantee. 6d. bottles **5/9** doz., **14/-** pint. ...
„ **Fumigator.** Copper cup. complete, **9d.** ... ...
„ **Hand Fumigator, 2/9** each. ... ...
„ **Powder Diffuser, 6d.** each .. ..
„ **Tobacco Powder.** Specially prepared (introduced 1888), **6d.** per tin ... ...
„ **Westite.** The first and best slug and germ killer, **6d.** per box to **20/-** cwt. ... ...
„ **Beetle Killer Powder, 6d.** per tin ... ...
„ **Plant Pot Crocks.** For perfect potting, prevention of insects into pot, etc., **2/9** per 100 ...
„ **Fertiliser.** Perfect plant food. Has stood the test for 20 years, **6d.** per box to **20/-** cwt .
„ **Watering Can Spreaders.** Fits any watering can and gives a splendid spray, **3d.** each ...
„ **Weeder.** Saves weary weeding, for a lady can uproot hundreds of weeds per hour, **2/6** ea.
„ **Lawn Sand.** Has stood the test for 25 years, and now improved, **6d.** per tin to **20/-** cwt...
„ **Weed Killer.** Best and cheapest for killing weeds on walks, etc. Introduced 1888. **1/6** tin
„ **Aluminium Labels.** When written on with lead pencil the wording is legible and indelible. Founded on the 25 years' experience with the West's Patent Label. **1/6, 2/-** & **3/-** per 100
„ **Layering Pegs** and **Verbena Pins, 9d.** per 100 ... ...
„ **Greenhouse Shading.** Introduced in 1888 and still the best. Green and cream, **9d.** box
„ **Garden Cuffs.** Keeps the coat cuffs clean. No gardener should be without them, **6d.** pair
„ **Flower Holders.** For button holes and ladies' sprays. The flowers are gripped and held in watertight nickel tube, so that the lady's may be worn downwards { Gent's, **7½d.** Lady's **10d.**

THE ACCENTUATION OF GARDEN FEATURES.

It is a mistake to add other features to a garden until those that already exist are, as far as possible, perfected. Many a half-filled rockery, ill-kept rosery, and unrepresentative water garden may be found even upon estates where floriculture is regarded rightly as one of the fine arts.

Perhaps in lesser pleasure grounds it is the rosery that most often needs improving: when varieties prove unsuccessful, owing to peculiarities of soil, climate, or position. They should never be left to struggle on, the subjects of disease, but should either be sacrificed altogether or removed to kitchen garden borders, waste land, or shrubbery spaces, where possibly their requirements might be satisfied, and they prove capable of yielding fair flowers after all. Occasionally new varieties of roses prove disappointing, or of colours that clash with their neighbours; these also should be moved to other quarters. A rosery needs to be viewed as a whole, so individual roses, even if charming, that spoil the general effect, ought to be transferred to localities where their merits will prove useful. Weedy ground in the rose beds sometimes reproaches the gardener; when no carpeting plant is permitted weeds are certainly terrible to keep under during wet periods of mild weather.

Rockeries should not possess any bare pockets or expanses of soil, while the presence of a dead or dying alpine here and there quite spoils the appearance of hosts of the beautiful living! For smallest spaces there are gay coloured miniature perennials in plenty: Potentilla villosa, with its silver-haired leaves and yellow flowers, is but three inches high; so, too, are Primula viscosa (rose), Primula viscosa nivalis (white); Saxifraga juniperifolia, with elegant foliage and spikes of yellow; Saxifraga coriophylla, a mixture of silver and snow; Sedum Ewersi, pink; Soldanella montana, fringed, and pale blue; and Gypsophila cerastioides, white, veined with red. When a rock garden is lacking in sufficient tall plants it presents a very unfurnished appearance; I always advise a free planting of the smallest-blooming kinds of perennial asters, since it is generally in autumn that rock plants blossom least, and the graceful effect of these light-growing "daisies" proves of great value. Liliastrums, montbretias, schizostylis, Linum narbonense, L. maritimum, L. hologynum, and L. flavum, statices, Ranunculus amplexicaulis, and the grass-leaved Sisyrinchium grandiflorum (purple), and S. grandiflorum album, are admirable light growers of considerable importance.

The water garden, to be perfect, must imitate the lavish planting of Nature; we do not find bare soil in naturally moist ground, but rather a prodigality of blossom and leaf, the most minute mossy subjects keeping their place without difficulty at the feet of giant reeds, rushes, and other robust growers. Immediate improvement results from the planting out of seed-raised Artemisia annua, a feathery green foliage plant that becomes covered after awhile with fluffy yellow florescence of very long duration. This hardy annual grows rapidly, reaches a height of three feet, and does not object to a very damp soil. Permanent improvement can be carried out with irises of many sorts, including the great yellow water iris, with solidagos, spiræas, Ranunculuses aconitifolius fl.-pl. and speciosus, myosotis, Mimulus cardinalis, Gunnera manicata, and G. scabra (where space permits), trolliuses, astilbes, and calthas.

M. H.

NEW PLANTS, ETC.

◆

CYCLAMEN SALMON KING.

Under this title Messrs. Hugh Low and Co., Enfield, have now an excellent strain of cyclamen. The plants have a good habit, the leaves are neat and well marked, and the flowers rise well above the foliage, borne on stout stems. The flowers are of fine size and substance, and their colour is very bright reddish salmon, with deeper shading at the base. A.M., R.H.S., February 11; Messrs. Hugh Low and Co., Bush Hill Park, Enfield.

MESSRS. HUGH LOW AND CO.'S NEW SALMON KING CYCLAMEN.
Flowers large, the colour rich reddish-salmon.

CYMBIDIUM LADY COLMAN.

This fine new hybrid is the result of crossing C. eburneo-Lowianum with C. Traceyanum. The latter has lent size to the former, and has modified the colour. The flowers are of large size, and four or five are produced on a spike (See p. 133), though doubtless as the plant gains strength the spikes will be larger. The ground colour is creamy-white tinted with green, and on this are faint broken lines of red-purple. The bold lip is white with red-purple markings. A.M., R.H.S., February 11. Mr. W. P. Bound, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

DIACRO-CATTLEYA COLMANÆ.

A most interesting and pretty hybrid raised by crossing Diacrium (epidendrum) bicornutum and Cattleya intermedia nivea. The habit of the plant closely resembles that of the Diacrium parent, and the spike is similarly produced, erect, and bearing three buds and one expanded flower. The latter is white, three inches across, and its shape shows the influence of both parents. The lip has a pale creamy disk, and a very pale tinge of pink at the apex. A.M., R.H.S., February 11; Sir J. Colman, Bart., Reigate.

LYCASTE SKINNERI ORION.

A beautiful and shapely variety of this old favourite orchid. Sepals blush-coloured; petals rosy-red with white markings; lip white. A.M., R.H.S., February 11. Mr. Whitelegge, gardener to J. Bradshaw, Esq., The Grange, Southgate.

SOPHRO-CATTLEYA ANTIOCHUS RUBRA.

This form of the hybrid between S.-c. Cleopatra and C. Warscewiczi differs from the original in having more deeply-coloured sepals and petals, and a very rich ruby-purple lip. The flower opens out well, and is very effective. A.M., R.H.S., February 11; Messrs. Charlesworth and Co., Heaton, Bradford.

Beurre Rance Pear.—This variety is not always a success for dessert, as from some soils it is gritty, but I let the fruits hang on the trees until very late; indeed, they had one or two degrees of frost on them before they were gathered in November. They are now ripening in the fruit-room, and are sent to the dining room daily, where they are much appreciated. It is a very juicy and sweet pear, and valuable at this date. The tree is of vigorous growth, and generally bears a fair crop of sizable fruits, if planted against a south wall.—T. W. Birkinshaw.

EARLY PEAS ON WARM BORDERS.

Not all gardens are provided with sufficient glass structures to grow certain classes of early vegetables in, therefore recourse must be had to other means, whereby growth may be advanced by a week or two. Since the days of cheap glass market growers have been able to put the finest of early vegetables on the market much in advance of supplies in private gardens, and this sometimes causes unpleasantness, as it is difficult to explain that houses by the acre are put up specially for these early crops, peas being one of them.

Though glass may not be provided wherein these early vegetables can be grown, much can be done by way of forwarding them in their early stages, and by taking the precaution to protect them later on in the season when planted in the open ground. For many years we have given up growing the old round-seeded varieties of peas, as we find the marrowfats, though not quite so hardy, may be had as early by sowing the seed under glass and protecting the young plants until it is safe to transfer them to the open ground. We use about five hundred four-inch pots for raising the early batch for planting on warm borders. This number is sufficient to take five pints of seed, and to plant twenty-five rows each twelve feet long. Most gardeners have a warm south border on which they can grow a few early peas, but the quantity grown must be regulated by the requirements of the establishment and the amount of space available. A pint of peas contains between eleven and twelve hundred seeds, therefore if a hundred pots are prepared by filling them three parts full with rich soil, there will be sufficient peas in a pint to allow about twelve seeds for each, and sufficient room for them to be placed about an inch apart. When the seeds have been placed in the pots cover them with fine soil. The pots may then be stood in a cold peach house, vinery, or frame, where they can remain until the plants are about an inch high, when they should be freely aired whenever the weather is favourable, to harden them off previous to planting out.

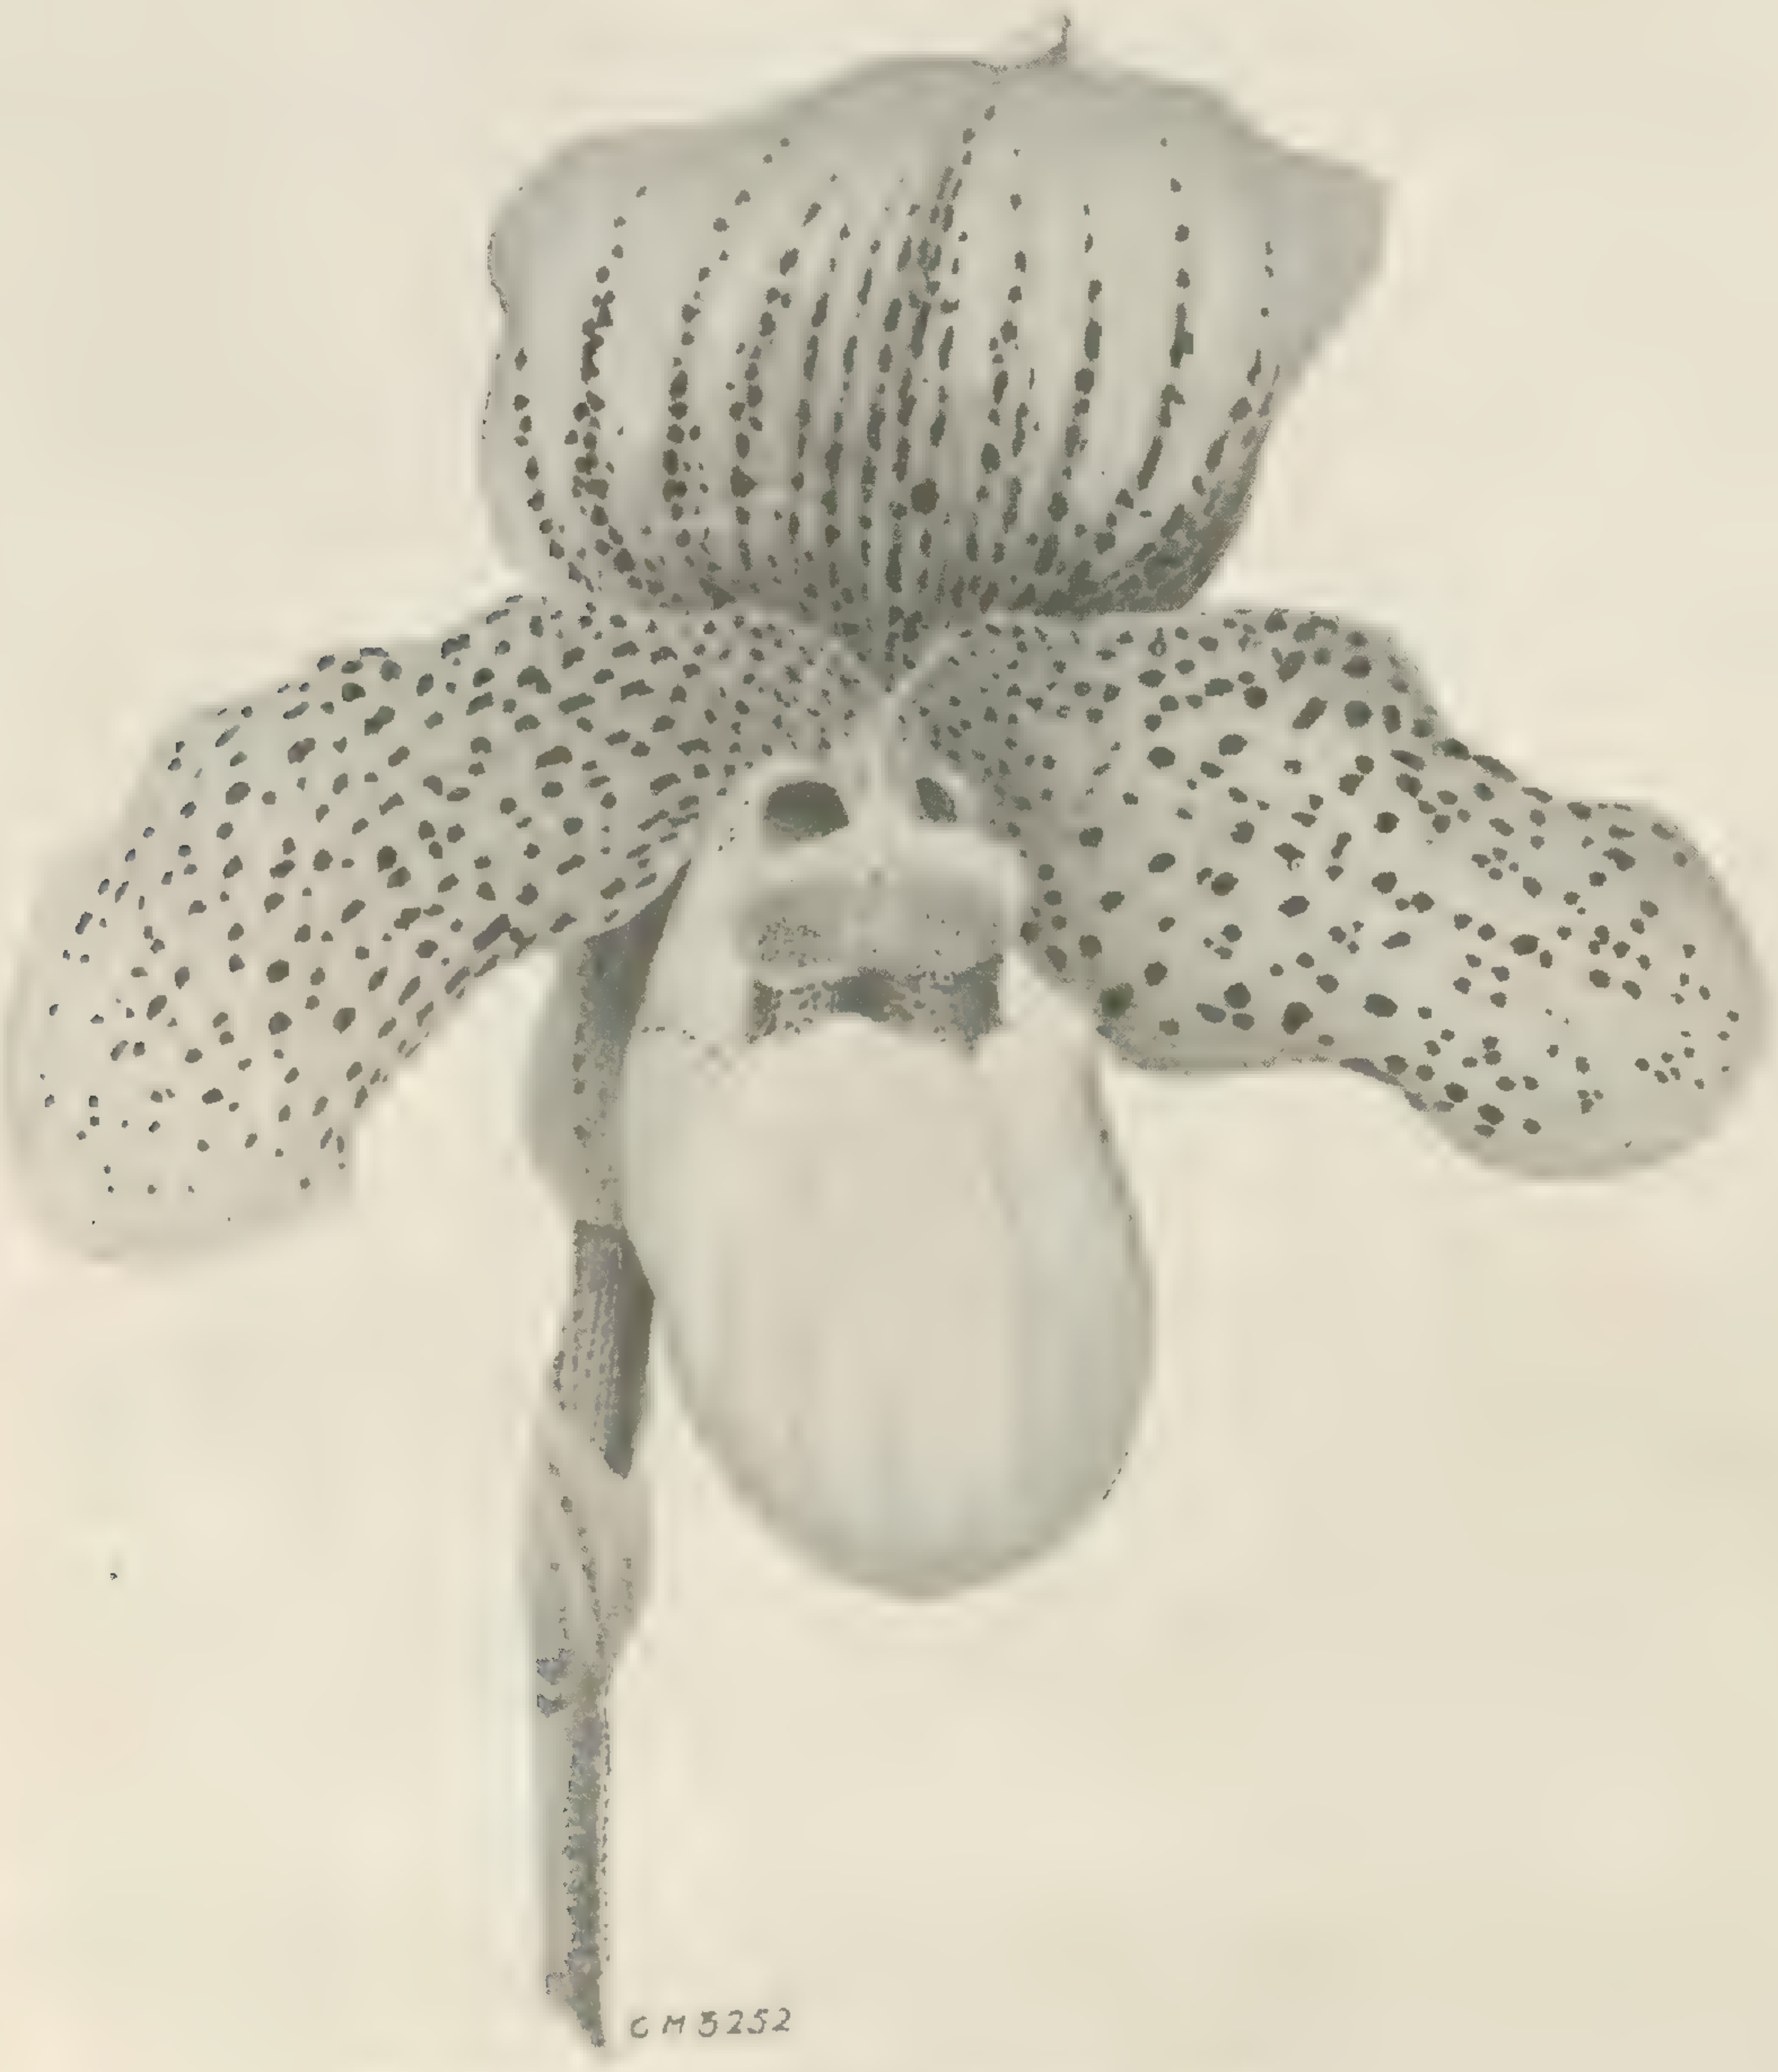
We sow about the first or second week in February. Dwarf kinds are used for early borders, as these may be planted closer together, though I am no advocate for close planting, as there is nothing gained by it. If the soil has been well prepared what are termed dwarfs should grow from two feet to two feet six inches in height. I have seen William Hurst and Chelsea Gem go up near three feet, and well clothed with pods for the greater part of the length of the haulm, therefore it is best to allow not less than three feet between the rows, so that light may be available on both sides. Early lettuce may be planted between the rows as soon as the sticks are put to the peas. For narrow borders we grow such kinds as Chelsea Gem, Early Forcing, World's Record, Little Marvel, Pioneer, and the like, while for the open ground taller kinds are grown, such as Gradus, Edwin Beckett, Early Morn, and Early Giant.

As, however, we are now dealing with warm borders, it is well to confine oneself to remarks connected therewith. Seed that is sown the first week in February and treated as advised should produce plants ready to put out the first week in April, or a little earlier should the weather be favourable. There being only twelve plants in a pot these should be sturdy and well rooted, therefore should there be no check to growth these will soon make headway. We put sticks to them as planting proceeds, as these will afford some protection against the cold winds should there be any at that time. The taller varieties should be sown a week later, as these grow much faster than the dwarf ones. It is useless to try to grow good early peas unless the soil has been well prepared, i.e., deeply dug and liberally manured. If it can be dug in the autumn so much the better, but this is not at all times convenient, as trees against walls have to receive attention, and not infrequently there is a winter crop on the ground. These early sowings are, as a rule, gathered before the soil becomes very dry, but finer results will be obtained if the plants are liberally treated while they are growing, for often the month of May is dry, therefore give them a soaking once a week with liquid manure.

I am no advocate of dwarf varieties that cannot be induced to grow more than a couple of feet, for this height, even in pots, is not inconvenient, and most so-called dwarfs will reach this height if liberally treated when young.

In low-lying districts it may be necessary to protect the plants when in bloom, as late frosts are sometimes very injurious, but this can readily be accomplished by spreading a piece of thin canvas over them at night. H. C. Prinsep.

Buxted Park Gardens.



CYPRIPEDIUM DOM CARLOS REX.
Flowers white, with purple markings.

CYPRIPEDIUM DOM CARLOS REX.

One of the most distinct of the several hybrid cypripediums raised from the interesting C. Godefroyæ leucochilum is C. Dom Carlos. The second parent was C. Lawrenceanum, this lending size and breadth to the substance and roundness of the other parent. The ground colour of C. Dom Carlos is creamy-white, with a tinge of pale green over the dorsal sepal, but the whole of the flower is pleasingly strewn with very fine red-purple dots. An Award of Merit was granted this hybrid on December 13, 1904, but at the Temple Show of 1905 the same exhibitor, Mr. Chapman, gardener to N. C. Cookson, Esq., Oakwood, Wylam-on-Tyne, showed a finer form of the same hybrid, calling it C. Dom Carlos Rex. In this the flowers are larger than in the type, and the ground colour is whiter, while the spotting and the shading of the lip are bright purple. The illustration serves to show the character of this handsome and interesting seedling that has proved so amenable to cultivation at Oakwood. C. Dom Carlos Rex was awarded a First Class Certificate by the Royal Horticultural Society on May 23, 1905.

Pruning Young Trees.—The theories set forth are somewhat perplexing to some of the more inexperienced growers. Some advocate no pruning the first year, and do but very little after. My advice is to prune moderately annually. Young standards should be very carefully attended to for a few years, first selecting from three to five young shoots, as equidistant as possible, to form the main or permanent branches of the trees: prune each shoot, say, from 10 to 15 inches in length, always cutting just above a bud pointing outwards, and where the next year's young growth is required. This should be repeated annually for a few seasons, and any young shoots not required may be shortened back to within a couple of inches of the base. As the trees increase in size, other shoots may be left to fill up and form a well-balanced head, after which only a slight thinning of useless wood will be required.—H. Markham.
Wrotham Park Gardens.

HOLLYHOCKS FROM SEED.

In making a brief reference to hollyhocks for the purpose of showing how readily a stock may be raised from seed, one might well say with John Parkinson, "I shall not neede to make many descriptions of hollihockes, in regard the greatest difference consisteth in the flowers, which are in some single some double, in some of one colour and in others of other colours." Hollyhocks have, in common with many other flowers, been greatly improved by the untiring efforts of florists, but they have not been so greatly altered in the process as in the case of some other subjects that were regarded with much favour by flower lovers in the nineteenth century. Their habit is much the same as when Parkinson wrote his "Paradisus" three hundred years ago, and, as will be seen from the foregoing extract, there were then, as now, both single and double-flowered varieties. The colours would appear to have been much the same in their main lines, but during the last century the raisers, by means of skilful crossbreeding and judicious selection, succeeded in obtaining a race in which the principal colours were more pleasing and effective than they were at the commencement thereof, and in creating a considerable number of intermediate shades of the most charming character.

AN EFFECTIVE GROUP OF SEEDLING HOLLYHOCKS. [Photo: F. Mason Good.

Quotations might well be made from the old writers who had a predilection for these flowers, in support of their great value for beautifying the gardens of all classes, but the object of the writer is not so much to sing their praises as to show how easily the plants can be raised, and how the cultivator may checkmate the dreaded disease. It may, however, be said that the hollyhock is equally suitable for the cottage and the ducal garden. Nothing could well impart a greater charm to the cottage garden than a few clumps of hollyhocks, and no hardy plants could produce a more striking effect on the terrace garden of a stately mansion than these when in a robust state of health and judiciously arranged in bold groups. Hollyhocks are also of much value for the herbaceous border, and they are decidedly effective when arranged in open spaces along the front of the shrubbery border. In whatever position they are placed they must enjoy full exposure to the sun, and have a rich root run.

There are several ways of propagating these plants, but the only one to which reference will now be made is the raising of seedlings. This method of propagation is recommended because seedlings possess so great a degree of vigour that they are not liable to suffer materially from the attacks of the fungus causing the disease, which in so many instances is most destructive in its effects on plants raised from cuttings and eyes. Plants can be raised and flowered well within twelve months, and those raised from seed that has been saved from a good strain can be depended upon to produce flowers of good form and pleasing in colour. There is no difficulty in obtaining seed saved from strains of undoubted excellence, and at a moderate price. There is no occasion to express an opinion on the relative merits of double and single varieties. It is simply a matter of taste, and cultivators should grow the section which they or their employers prefer. Both singles and doubles are extremely beautiful, and as they are equally useful for the production of bold effects, those who have not a special preference for either should grow them in about equal proportions.

Seed may be sown in February in heat, and in June in the open, but seedlings raised from seed sown during the current month will, with good cultivation, produce finely developed spikes at the end of the summer or early in the autumn. The seed should be sown in pans or shallow boxes that have been efficiently drained, and filled with a light rich compost. To avoid waste of seed or injury to the seedlings from overcrowding before they are of a suitable size for transplanting, place the seeds an inch apart, and cover to the depth of about a quarter of an inch with fine soil. When sown in this way there will be no occasion to disturb the seedlings until they are touching each other, and then they will be of a convenient size for transplanting. A temperature of about 65 degrees will be the most suitable for promoting a quick germination, and until the seedlings are making their appearance above the surface a piece of paper should be laid over the pans or boxes. It should then be removed, and a few days afterwards the boxes or pans be removed to a light position near the glass.

The next stage is to prick the seedlings off into three inch pots, and this should be done when they have made sufficient growth to touch each other. Keep rather close and shaded for a few days, gradually inure to light and air, and then remove to an unheated frame or pit, which, after a few days, should be freely ventilated. Early in May will be a good time to transfer the plants to the beds and borders in which they are to bloom, and if they become pot-bound two or three weeks before they can be planted out shift into six-inch pots. The best compost for potting is one consisting of turfy loam four parts, well decayed manure two parts, and leaf-mould one part.

With regard to planting out, the cultivator will be guided by the condition of the plants and the state of the weather. It will be better to wait for a week or ten days than to put them out before they are thoroughly hardened, or when the weather is decidedly unfavourable. They should be arranged in groups of three or four plants each, and the sites selected must previously be liberally enriched with manure, and be deeply dug.

O. P. Q.

POLYGONUM AMPLEXICAULE VAR. SANGUINEUM.

The aggressive weediness so abundantly manifest in many species of polygonum, and which is not altogether wanting in typical P. amplexicaule, finds no place in a pretty form recently named sanguineum. I have had a colony of it under cultivation for four seasons, and can recommend it as a refined plant of attractive colouring peculiarly fitted for free grouping on the shrubbery margins, in the bolder types of rock gardens, and for the broad herbaceous border. The habit is semi-prostrate, literally a loose carpet of trailing stems a square yard in area; the leaves are broadly arrow-shaped, and pea green throughout summer, changing in mid-autumn to the brightest autumn tints. The flowers are in stout, erect spikes, and are coloured blood-red, the seed vessels which follow the flowers being scarcely less brilliant, and at the distance of a few yards flowers and seed spikes appear exactly alike.

The plant's hardiness and easy adaptation to all manner of soils and situations are helpful features the landscape gardener cannot afford to ignore. It will thrive in the poorest of soils, and should prove of considerable service as a free carpeting plant for beds of Magnolia stellata, shrubby spiræas, and other shrubs whose bases are not usually well leaved. This polygonum rarely exceeds a foot in height, does not run inordinately at the root, and is in no wise intractable. The flower spikes are very attractive cut and mixed with their own foliage in vases, but are seen at their best grouped on the shrubbery margin, giving one a light haze of red in the distance that deepens with advancing autumn to crimson, the golden-yellow, crimson-edged leafage joining in the colour display. G. B. Mallett.

Aster sinensis.—This is one of the most, if not the most, pleasing of the recently introduced types of annual asters. Its single flowers, which are white, blue, and other colours, are much more useful for decorative purposes in a cut state than the other types, the effect produced in the garden being very pleasing. Anyone who has not yet grown the single forms of this aster should not fail to do so. It is well to plant in rich soil, and give them plenty of room. Here in 1905 on one plant I counted eighty-eight flowers and buds, besides a large number of lateral buds that were developing. The specimen was three feet wide, thirty-three inches high, and continued in bloom a very long time—in fact, until frost cut it down.—E. F. Hazelton, Knowsley Gardens.

VIVIPAROUS FERNS.

One great distinction between ferns and flowering plants is the general absence of such buds as in the latter we find in the axils of the leaves, i.e., at the points of junction of leaves and their supporting stems, main or secondary. If, for instance, we examine a tree, we invariably find an incipient bud in such situations, and it is one of the functions of the immediately adjacent leaf to nourish this bud, so that when the leaf falls, it is suceeded by an outgrowth originating from this bud and capable of producing a branch, or if separated and properly treated, of developing into an independent plant. In ferns, even if we select a large tree fern with immense wide-spreading fronds, we shall search in vain for any such buds, incipient or developed, the entire frond, however large, being in point of fact the equivalent of a single leaf, and not as in the branch of a tree a multitude of individual ones.

Ferns, however, do produce buds and in very varied ways. There is, for instance, the familiar Asplenium bulbiferum, so largely used for room decoration, upon the fronds of which there are produced under healthy conditions a large number of young plants, which appear, first of all, as minute pimples on the upper surface of the frond divisions. These then develop into somewhat scaly knobs, whence fronds speedily arise and unfold, and even when quite small will, in their turn, bear pimples and young plants, so that two generations may appear, both being entirely dependent upon the parent and grandparent. These last terms, however, are hardly correct, since the buds being asexual, i.e., not produced by any act of fertilisation, they are merely parts of the original plants. Under humid conditions it will be found on examination that these young plants do not merely consist of fronds, but that they possess a bunch of incipient roots, and hence it is only necessary to cut off the piece of frond to which they are attached, and insert it in soil, for the plant to establish itself without difficulty.

There are a number of allied asplenia which act similarly, and our common Harts-tongue (Scolopendrium vulgare), which is nearly related to this family, has produced several curious viviparous varieties, some of which bear bulbils, as these growths are called, on the edges of much-divided fronds, while one, S. v. cristatum viviparum O'Kelly, found in Ireland, produces them on the surface in precisely the same way as A. bulbiferum. It is also a very common occurrence with many other varieties of the Harts-tongue to find surface bulbils produced on accidentally crippled fronds, both on the stalks and on the damaged fronds. In all such cases these bulbils can be used for propagation by cutting off the bulbil with a piece of frond attached, and inserting it so that the bulbil touches the soil. The edges of pots in which other ferns are growing form capital sites for such insertions.

Woodwardia orientalis presents another example of superficial bulbil growths, but goes a step farther, since while all those cited above are firmly attached and require separation and special planting for propagative purposes, W. orientalis has its little plants so slightly attached that when they have formed two or three little fronds they are easily detached by friction with neighbouring foliage, and then, using their rounded fronds as parachutes, sail to the soil, right side up, and, if fortunate, root where they fall. W. radicans, a near relative, adopts a different plan. It has long pendulous fronds with one or two large fleshy bulbils near the tips, and these develop into fair-sized and consequently heavy plants, which bend down the tip until it touches the soil, into which they root. This fern is a type of a number of others which in like fashion bear rooting bulbils at their frond tips, and thus, as in the case of the so-called American Walking Fern (Camphosorus rhyzophyllus), stride, as it were, over the ground and propagate themselves.

Some of the prettiest examples of this kind are of the Adiantum or Maidenhair genus, such as Adiantum lunulatum, A. caudatum, and A. dolabriforme, all of which form beautiful hanging plants, the fronds bearing several generations produced successively in this way. Our native Shield Ferns (Polystichum) have produced numerous varieties of a viviparous nature, bulbils being developed more or less freely on the fronds and their subdivisions, not, however, on their surfaces, but at the points of junction of their subdivisions, forming in point of fact the nearest approach to the axillary buds of flowering plants. Most of the very finely divided varieties of P. angulare, the soft Shield Fern, are prone to produce such bulbils on the stalks near the base of the fronds, but the normal forms are never bulbiferous.

Cystopteris bulbifera affords an unique example in the viviparous line by producing bulbils provided with such a generous store of nourishment for their independent support when detached that they resemble oval green berries, larger sometimes than fat grains of wheat, and consisting of two lobes between which the bud nestles. These "berries" fall off, and, reaching the soil, give rise at once to decent-sized plants, so that under suitable conditions the fern becomes a weed. In addition to the forms of viviparousness described, most of which, as we have seen, are specific characters, and affect only normal plants, in some abnormal forms, or "sports," we find bulbils appearing on the frond backs associated with the spores. This has been found on several plumose varieties of our native Lady Fern, but in Lastrea prolifera, it is a normal character. Obviously, all these forms of viviparousness are beneficial to the fern by providing a means of survival as well as propagation should the parent plant be seriously damaged, and in this connection we may fitly close by pointing out that Nature has endowed some ferns, probably many, for the point has been little studied, with the faculty of producing viviparous buds from the remains of mutilated caudicles or crowns, whose original axis of growth has been entirely destroyed.

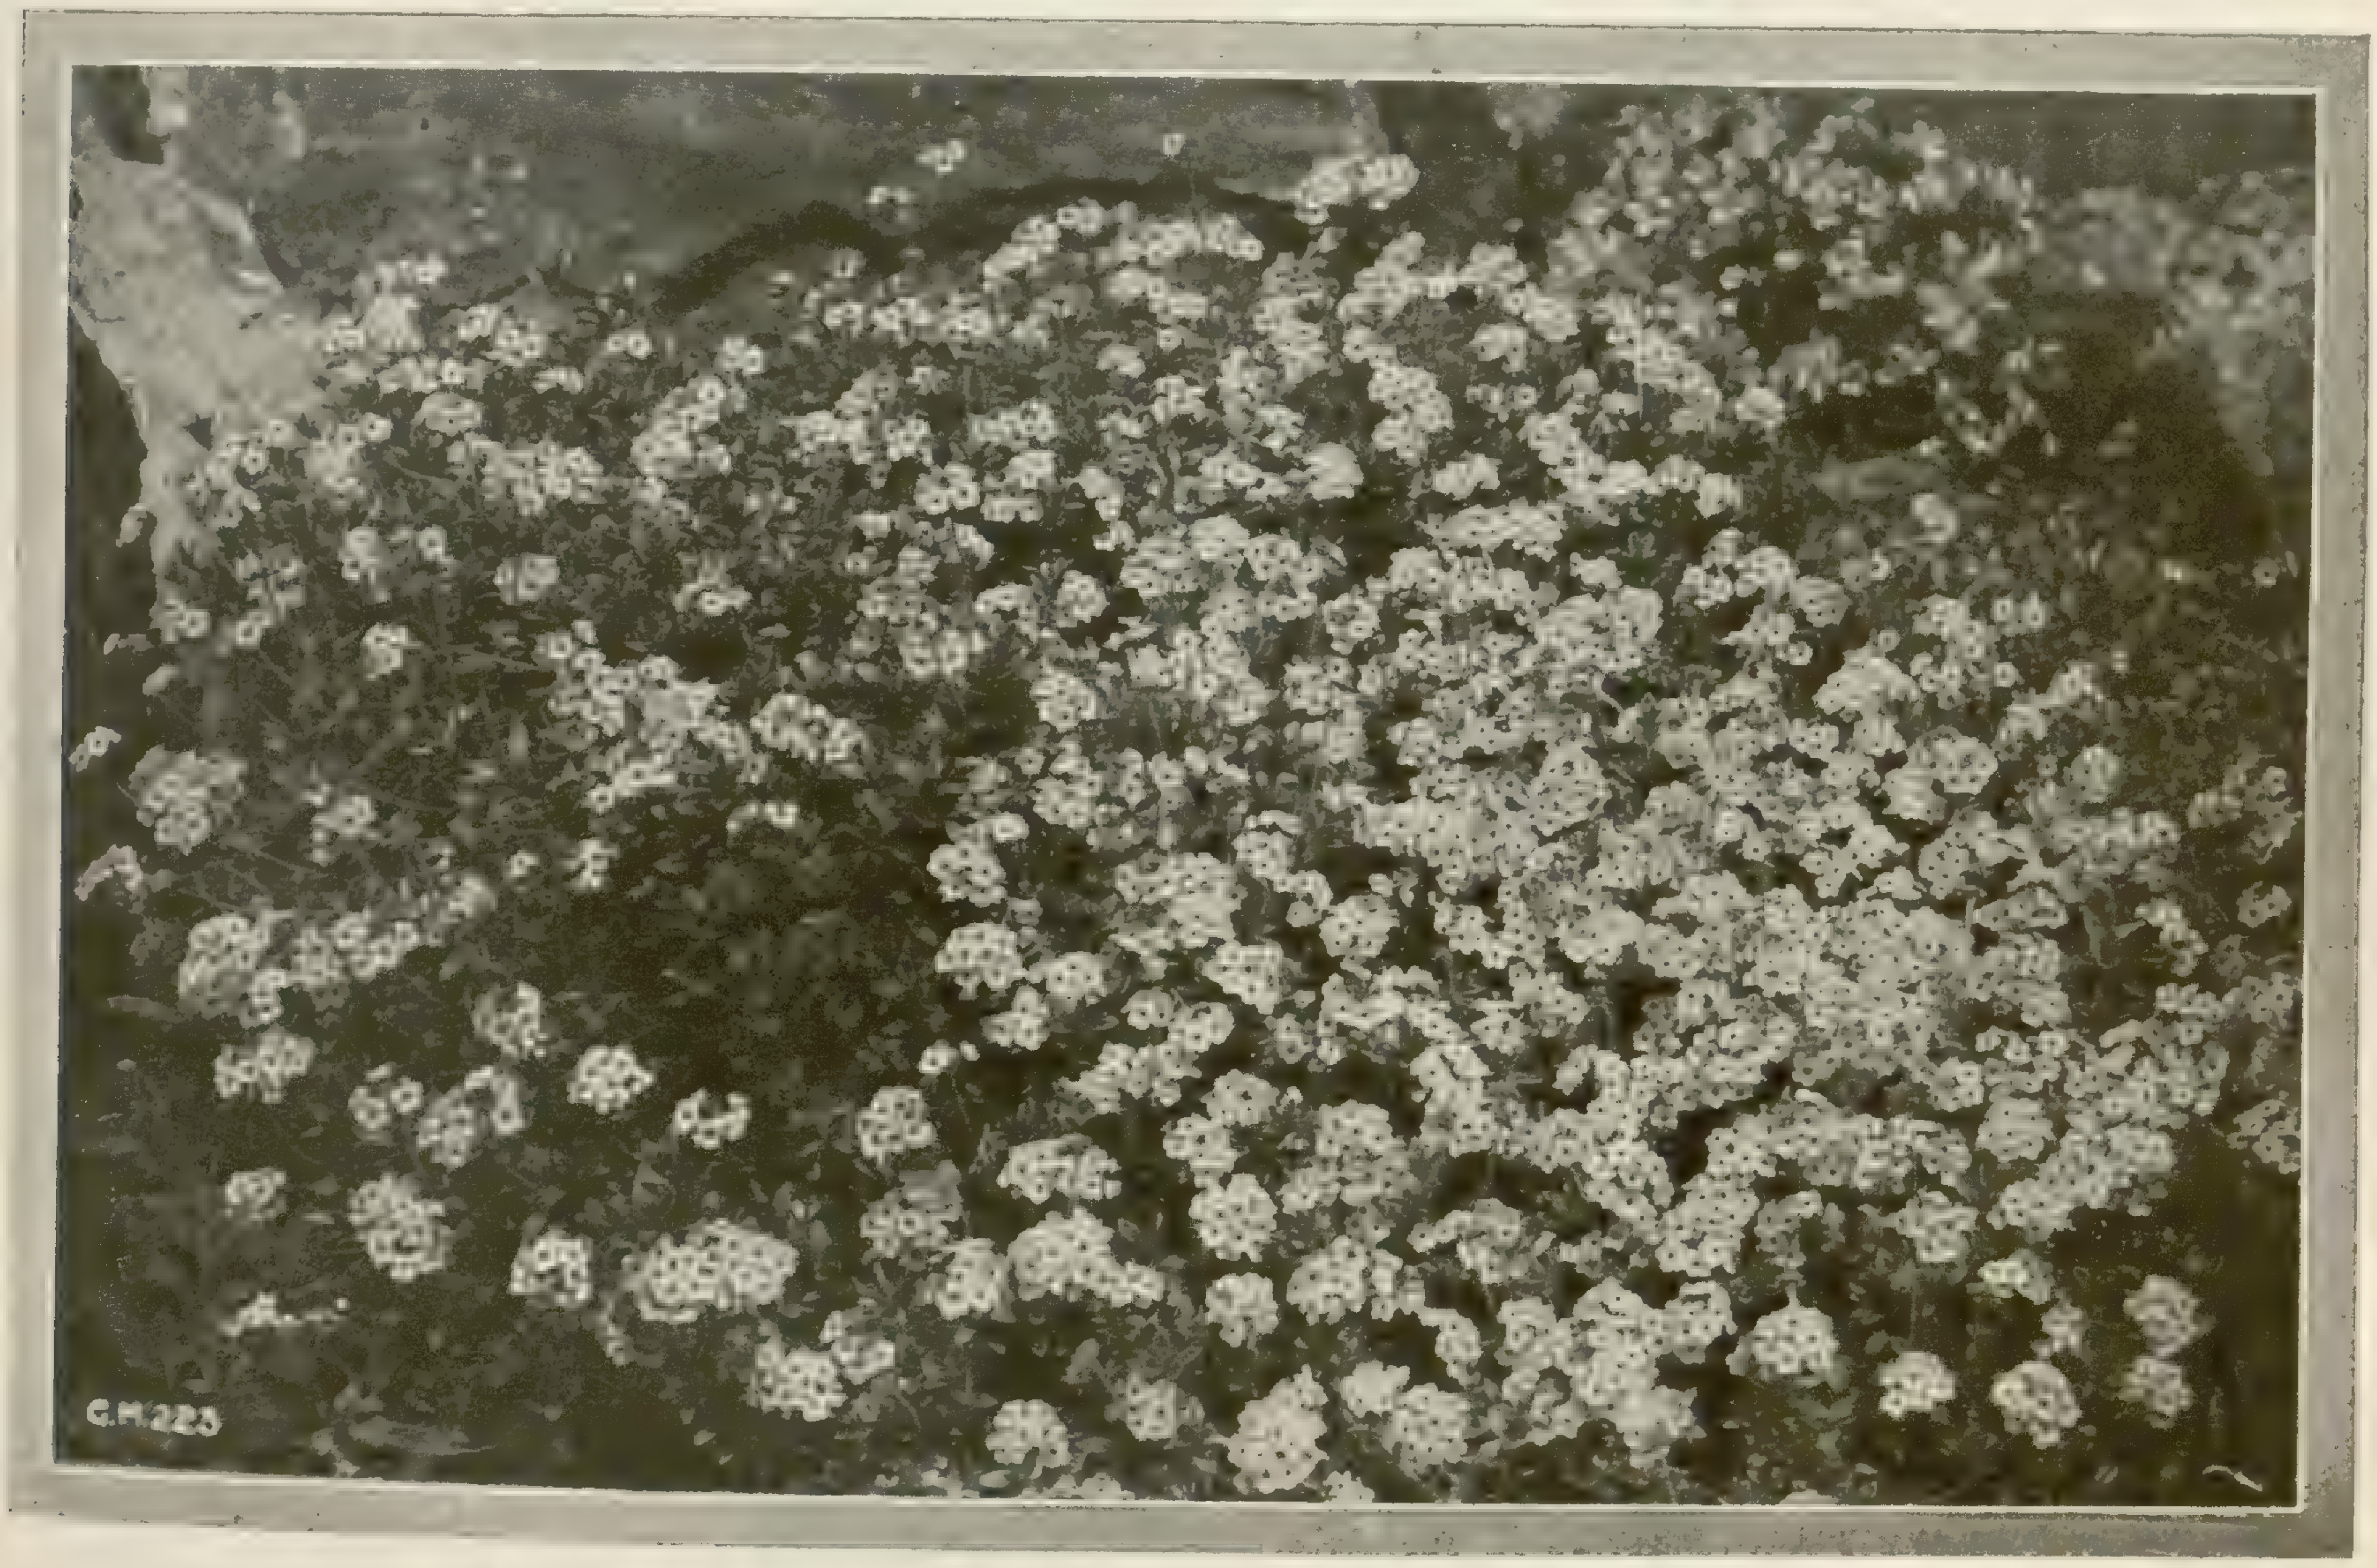
Thus we may take a crown-forming fern, such as a Shield Fern, and shave the entire growing centre away, apparently killing it, and yet placed in damp soil or cocoanut-fibre refuse, bulbils will be developed, and possibly scores of plants may in time result by subsequent careful separation. The late Mr. G. B. Wollaston told the writer of a case where a very rare and beautiful variety of Shield Fern had gone wrong and was treated by him in this way, and under warm treatment no less than eighty plants rewarded his apparent sacrifice of one.

Chas. T. Druery, V.M.H., F.L.S.

Damsons.—These are less grown than they should be, seeing that the fruits are exceptionally useful, and when bottled can be kept in good condition for some time. The trees are hardy, and can with advantage be planted to form screens for less hardy fruits. The heads need a little pruning annually, and the roots, after the trees are in full fruiting, should be fed.—H. Markham.

THE ANDROSACES.

These charming denizens of the Alps, the Pyrenees, the Himalayas, and other mountain ranges are among the most beautiful of rock plants when growing freely and blooming profusely. Unfortunately, however, they are not, as a race, easy of culture, for, although in certain gardens some species will flourish to perfection, the same plants will absolutely refuse to grow under apparently precisely similar conditions, even when treated with the most solicitous care. Our English winters, with their alternations of frost and damp are doubtless chiefly responsible for their disappointing behaviour. In their native lands, though the winter frost is severe, they are generally covered with a thick mantle of snow, which keeps them dormant and snug until it is melted by the strengthening sunshine.



ANDROSACE LANUGINOSA IN MR. FITZHERBERT'S GARDEN.
A beautiful alpine plant with silvery leaves, and bearing clusters of rose-lavender flowers.

As a preventive of undue winter moisture large panes of glass, fixed in a slanting position above the plants, will keep the rain from falling on their leaves, and, if they are of large size, a spare light tilted over them will give them adequate protection. Surfacing the soil with stones is also effective in rendering the foliage less liable to become saturated. A deep root-run of porous soil, well mixed with rough grit and stone chippings should be provided, so that the root-fibres may remain cool and moist while the foliage and flowers are revelling in the hot summer sunshine, a good compost being peat, leaf-mould, and loam in equal proportions, though specimens often do well in sandy loam. All species are partial to having stones sunk deeply in the soil about them, round which the roots may creep, and some can only be satisfactorily grown in rock fissures.

Of the Himalayan species the following are the most noteworthy: A. lanuginosa—This is without doubt the loveliest of the androsaces when seen in large masses covered with flower. Its rosy-lavender blossoms, with yellow eyes, commence to expand in May, and are at their best about midsummer, but continue well into the autumn, it being no uncommon occurrence to see an example still in bloom in November. The silky foliage is greyish-white in colour, and large specimens have the appearance of cascades of silver falling over the rocks. The mass here illustrated, which measures over four feet each way, is the outcome of two tiny plants put out from thumb-pots three years ago, on a sunny bank, in soil mixed with a large proportion of small stones and grit. In neighbouring gardens this androsace has refused to grow. As an instance of the capriciousness of this species it may be mentioned that what was probably the finest example in England, which formed a cataract of bloom over six feet long and three feet wide down a series of rocky ledges, and whose owner described it as one of the easiest of rock plants to grow, suddenly died a few years ago, since which time it has absolutely refused to live in the same garden, although good rooted cuttings have been annually planted and fresh compost of the most approved description has been provided.

Androsace lanuginosa makes prostrate stems a foot or so in length. Cuttings may be made of these, and, if they are placed in pure sand and kept close for a short time, will soon root. Planted in the spring, a few inches apart, these will soon form an effective mass. Old stems cut back make stronger growth, and bear larger heads of bloom. The best position for this androsace is one where its growths may hang over perpendicular rocks. A. sarmentosa is of stoloniferous growth, and has round, silvery-green rosettes ramifying from each other that often cover many feet of ground. If stones are placed on the threadlike runners these will root into the soil. The verbena-like flowers are pink in colour with yellow eyes. The foliage is very woolly, and the plants often suffer much from damp in wet winters. They should therefore be covered with glass in order to prevent the leaves being affected by overhead moisture.

A. Chumbyi is a variety of the last-named, with neater growth and brighter-coloured blossoms. A foliosa is a coarse-growing species bearing large rosy-lilac flower-heads on stems six inches or more in height. It is of comparatively easy culture. A. sempervivoides is a pretty plant from Western Thibet, not so silvery in foliage as those already mentioned, with neat growth and rose-pink flowers.

Of the Alpine section some of the species are among the most difficult of all rock plants to grow satisfactorily. Of these A. imbricata and A. glacialis may be singled out as especially impatient of garden culture. A. imbricata, or argentea, lives at great elevations in the dry crevices of sunny precipices, forming little rosettes of grey foliage which bear white flowers, the roots of the tiny plants often penetrating many feet into the rock. In this country the only hope of success lies in planting in a rock-fissure, but it is generally impossible to spread out the long roots evenly in such a confined space, and it is therefore usually advisable to build a rock-crevice. Where this is done large masses of stone should be used, and the soil rammed tight, so that the action of the winter frosts and rains may not displace the material.

A glacialis, or alpina, is found growing in rocky débris at a great elevation. It is unlike A. imbricata, which lives in the narrow chinks of the cliffs, an easy plant to collect, but rarely lasts more than a season or two in England. A steep, sunny slope and a compost of gritty peat mixed with sandstone chips offer the most likely conditions for its well-being. Its flowers are soft rose-pink and large masses in profuse bloom afford beautiful pictures in the high Alps. A. helvetica, with white flowers, is less exacting than the two last-named, as are the white yellow-eyed A. pyrenaica and the yellow A. Vitaliana, while the pink A. carnea and the rose A. Laggeri are of comparatively easy culture.

A. chamæjasme, with blush-white flowers, is a limestone plant, while A. obtusifolia, white with yellow eye, is a lime-hater and a granite-lover. A. Wulfeniana and A. ciliata, from the Tyrol, bear pink flowers. A. villosa, a Pyrenean plant, is very lovely, and has blush-white blossoms, and other European species are A. arachnoidea, A. coronopifolia, A. cylindrica, and A. pubescens. S. W. FITZHERBERT.

CHIMONANTHUS FRAGRANS

Among the several shrubs that blossom during the first weeks of the year there are five or six remarkable for the fragrance of their flowers, in fact it is doubtful whether their delicious perfume is equalled by a similar number of shrubs selected from the many that blossom two or three months later. Of these few, the Winter Flower (Chimonanthus fragrans) is one of the most fragrant. It is a native of China and Japan, and is related to the American genus, calycanthus; in fact, Linnæus placed it among the calycanthuses with the name of C. præcox. Though perfectly hardy it is often given a position on a wall, so that the flowers are afforded some little protection.

When grown against a wall the best culture to adopt is that of a vigorous spurring back as soon as the blossoms fade; this encourages the production of long young shoots, which produce blooms from almost every bud. When cut flowers are required these shoots, two feet or more long, will be found excellent for arranging with other flowers on account of the perfume. Grown in the open border, bushes six or eight feet high are formed, with somewhat stunted branches, which bear flowers freely. When out of blossom there is nothing uncommon about the shrub, but when the flowers are fully expanded in January the plant is much admired. The flowers may have either cream or golden sepals, with brownish petals. There is a variety, grandiflora, with rich golden flowers, larger than those of the type. It is a difficult shrub to propagate, and the type is usually increased by means of seeds, whilst the variety is grafted on stocks of the type. W. DALLIMORE.

Narcissus obvallaris.—For pot culture in the greenhouse this sturdy trumpet daffodil is one of the most attractive. I have just now some of them flowering in a quite cool greenhouse, where the average night temperature has been about 45 degrees. It is surprising the progress the bulbs have made in this temperature, considering they were only introduced to the greenhouse about the end of December. The rich golden-yellow of the expanded trumpet is very beautiful, and, indeed, for colour, this variety has no equal among the early daffodils. One point in favour of thus gradually bringing these into flower is that the plants quickly recover when planted out again, while those that have been subjected to a forcing temperature take several years to recover. These daffodils are so easily grown that every amateur should try a few pots in the greenhouse in this way. Grown thus they last a long time in good condition.—T. B. FIELD, Ashwellthorpe Gardens.

SWEET PEAS IN CLUMPS AND ROWS.

For the main batch of sweet peas to supply cut flowers or for the decoration of the garden, experience proves that there is no sowing period quite so good as about the middle of March. Earlier sowings have a tendency to rot, the white-seeded varieties especially; later ones may be overtaken by hot, dry weather before they send their roots well down in the cool manure provided for them.

By the middle of March the soil is generally in such a condition that sowing may be performed under almost ideal conditions. Mellowed by exposure to winter's rains and frosts, it breaks down under fork or rake to a beautifully fine mould, delightful to work, and an ideal nursery for the seeds. On the other hand, the soil still retains a goodly quantity of moisture, and this acted on by the increasingly powerful sun, sets up germinative conditions of the highest order. If a mid-March sowing is supplemented by another at the middle of April, or as soon as the first sowing is well through the soil, the chances of failure are very remote, and those of a fine and a prolonged display correspondingly good.

If the soil is still in the rough condition in which it was left at the winter digging, a fork should be used to break it down. A fork is infinitely to be preferred to a rake for this purpose as it lightens and aerates the soil, whereas a rake compresses it, and closes the interstices. On soils that are naturally light and loose I strongly advise a good treading before sowing the seed, as there is no question that the sweet pea likes a firm root run. Tread well over the whole plot, then with the fork loosen up and level the top three or four inches of the bed. On heavy soils treading will not be needed, but the fork should be used to break down clods and make the surface fairly level.

If possible, a day or two should intervene between this forking and the sowing of the seed; it is so much more pleasant working when the soil does not cling persistently to rake, boots, and fingers. With the surface dry and crumbly proceed with the rake to prepare the stations for the seeds. If clumps are favoured, scrape away a basin-like depression about two feet wide and two inches deep. If rows are preferred, stretch the garden line, and with the rake make a shallow trench along its course, about a foot wide and two inches deep. The effect of these operations will be that the seeds, and ultimately the plants will rest in a depression a little below the general ground line. This is to ensure that they retain as much as possible of what rain falls, and to assist the application of food and water later on.

With regard to the actual sowing, it is now generally recognised that sweet peas give better results at a foot apart than they do at, say, three inches. To make sure of a crop it is the usual practice to sow at about the latter distance, and then thin out the plants as required, and although more trouble I think the following is a better plan. After the shallow trench has been made go along it and drop down two seeds, in pairs, at distances of about one foot apart all through the row. Next, go again along the row and press each seed down as far as it will go with the forefinger: those with tender fingers will find a blunt-ended piece of stake a capital substitute. When finished, cover the holes with the rake, and firm the soil over them with the back thereof.

For clumps this system is equally good, each clump being seeded, sown, and raked before another is begun. Labelling should follow sowing, each clump or each section of a row being labelled as the seeds are put in. In case any reader should think this system a long-winded and troublesome one, I would like to say that last year I sowed over 1,000 feet run of row in this way in a single morning, and found it quite pleasant work. After sowing, dust a little fresh soot over the site, and near woods and fields a few strands of black thread should be strained across the seeds to keep away birds.

There are two ways whereby the germination of a good percentage of the seeds may be secured, and these may be briefly mentioned. Mice, birds, and wireworms all have a great liking for sweet peas; the two former will carry them away wholesale, the latter will bore into them and ruin them. All may be checked, if not quite frustrated, by soaking the seeds in paraffin oil. Just how long they are soaked does not seem to matter much, as the oil has never been known to penetrate to the germ of the seed; but a few minutes will generally be sufficient. My practice is to throw the seeds into a jar of paraffin while I am getting the trench ready, take them out when the trench is finished, lay them in an earthenware saucer, and sow from that. I find this is enough to save them from mice and birds, though I have lost some from wireworm after this treatment. To make assurance double sure the damp seeds may be rolled in a little red lead before sowing.

The second way of ensuring or assisting germination is to nick a notch in the skin of the seed with a sharp knife. Only the black or dark-seeded varieties need this assistance, and it is a moot question with many growers whether they really need it this year. Last year the hot summer of 1906 had so hardened the seed coats that chipping was generally practised throughout the country; 1907 was nothing like so sunny, therefore the argument is that no nicking or chipping is required. However, I have already sown some hundreds of seeds in pots, and as I have had to take many of these up and chip them before they would germinate, I advise readers to adopt this simple precaution—at least with all expensive seeds. E. J. CASTLE.

DAPHNE MEZEREUM GRANDIFLORA.

The mezereon and its varieties provide a number of beautiful flowering shrubs that are of exceptional value, for they blossom at a time when few other shrubs are in flower. The type is well known by reason of its profusion of fragrant red blossoms, which make their presence known from a considerable distance during February and early in March by their delicious scent. The variety grandiflora, however, is less frequently met with though it has qualifications which warrant its extended culture. It is of sturdier appearance than the type, somewhat similar as regards height, with rather larger and deeper coloured flowers. As a rule flowers commence to open in October, through which reason the name of autumnalis is sometimes applied to the plant, but it is not until the early part of January that the majority of the blooms expand and throughout January branches are wreathed with the densely-clustered flowers, which are quite as fragrant as those of the type. As in the case of the species the flowers of this variety are succeeded by bright red fruits, which add a further period of beauty. Those who are fond of variety should obtain D. mezereum alba; this is recognised by its white flowers and golden fruits. W. DALLIMORE.

A WONDERFUL POTATO EXHIBIT.

Beyond all question, the splendid exhibit of potatoes arranged by Messrs. Sutton and Sons, Reading, at the Royal Horticultural Hall, on Tuesday, February 11, was the finest of its kind ever seen. Not only was it unusually attractive, but it was intensely interesting, the tubers being of good size and perfect shape and colour. To growers and exhibitors of potatoes the display was one of unusual educational value, for not only were the varieties, about two hundred, all shown in fine style, but they were true to character—a point of considerable importance. Moreover, the "seed" potatoes served a very useful purpose, as they indicated the most desirable size of sets for planting.

Spectacularly and horticulturally the exhibit merited and received the highest encomiums, but from another point of view, the scientific, it possessed great value. By no means the least interesting feature was the most remarkable collection of wild types of potatoes, and their crosses, numbering no less than seventy-nine. It is safe to say that no such display of the wild forms of the tuber-bearing Solanums has ever before been brought together. The gathering of such a collection must have taken years of patient work, and naturally the greatest interest was shown in them. Full details of these wild types and hybrid-seedlings raised from them are appended:

"Solanum tuberosum" (of Mexico) grown from tubers raised from seed received from Vermont Agricultural Station, United States, 1906.

"Solanum tuberosum" (another form from Mexico) grown from tubers raised from seed saved at Vermont, 1906.

Hybrid-Seedling — "Solanum tuberosum" (of Mexico) x Solanum etuberosum (of Chili).

Hybrid-Seedling — Solanum Commersoni (Dunal) (flowers white) x "Solanum tuberosum" (of Mexico).

Solanum polyadenium (Greenman) grown from tubers raised from seed received from Vermont, 1906.

Solanum Maglia (Schlechtendahl) grown from tubers received from Mr. Baker at Kew in 1886.

Hybrid-Seedling—Solanum Maglia (Schlechtendahl) x Potato of Commerce.

Hybrid-Seedling—Solanum Maglia (Schlechtendahl) x Potato of Commerce x Potato of Commerce.

Solanum etuberosum (Lindley)—pot culture. Grown from tubers received from the Royal Botanic Gardens, Edinburgh, 1886 and 1897.

Solanum etuberosum (Lindley) — open ground culture. Grown from tubers received from the Royal Botanic Gardens, Edinburgh, 1887 and 1897.

Solanum etuberosum (Lindley), Seedlings from pot culture.

Solanum etuberosum (Lindley), Seedlings from open ground culture.

Papa d'Amarilla—grown extensively on the Andes.

Hybrid-Seedling — Solanum Commersoni (Dunal) (flowers white), x "Solanum tuberosum" (of Mexico).

Hybrid-Seedling — Solanum Commersoni (Dunal) (flowers white), x Potato of Commerce.

Solanum Commersoni (Dunal), from Uruguay (flowers violet). A very interesting group consisting of plants of the Papa Silvestre, the wild potato of Uruguay, which Messrs. Sutton and Sons have lately received from a correspondent in Uruguay. The plants, of which five different consignments have safely reached Messrs. Sutton and Sons, were in each case collected in the wild state under various conditions of soil and locality, and very far from any cultivated land. In each case there is every reason to conclude that the several consignments of tubers represent one and the same species. With the first consignment Messrs. Sutton and Sons received a note from Senor Arechavaleta, Professor of Botany and Director of the National Museum of Montevideo, certifying that the tubers were the true Solanum Commersoni (Dunal), being in fact the plant introduced by Commerson in 1767. Senor Arechavaleta further stated that all the wild potatoes found in Uruguay were of one and the same type. In the "Histoire de la Pomme de Terre" by Monsieur Ernest Roze, Lauréat de l'Institut et de la Société nationale d'Agriculture de France, published in Paris in 1898, there appears on page 17 an engraving accurately representing the dried specimen of the original plant introduced by Commerson in 1767, and this engraving corresponds in every respect with the Papa Silvestre shown by Messrs. Sutton and Sons. It is noteworthy that the plants recently grown in France and England under the name of "Solanum Commersoni" have mostly, if not in every case, been of a different type, bearing white flowers.

Solanum Commersoni (Dunal) (flowers white).

Solanum Commersoni (Dunal), from Mr. Fitz-Herbert of Uruguay.

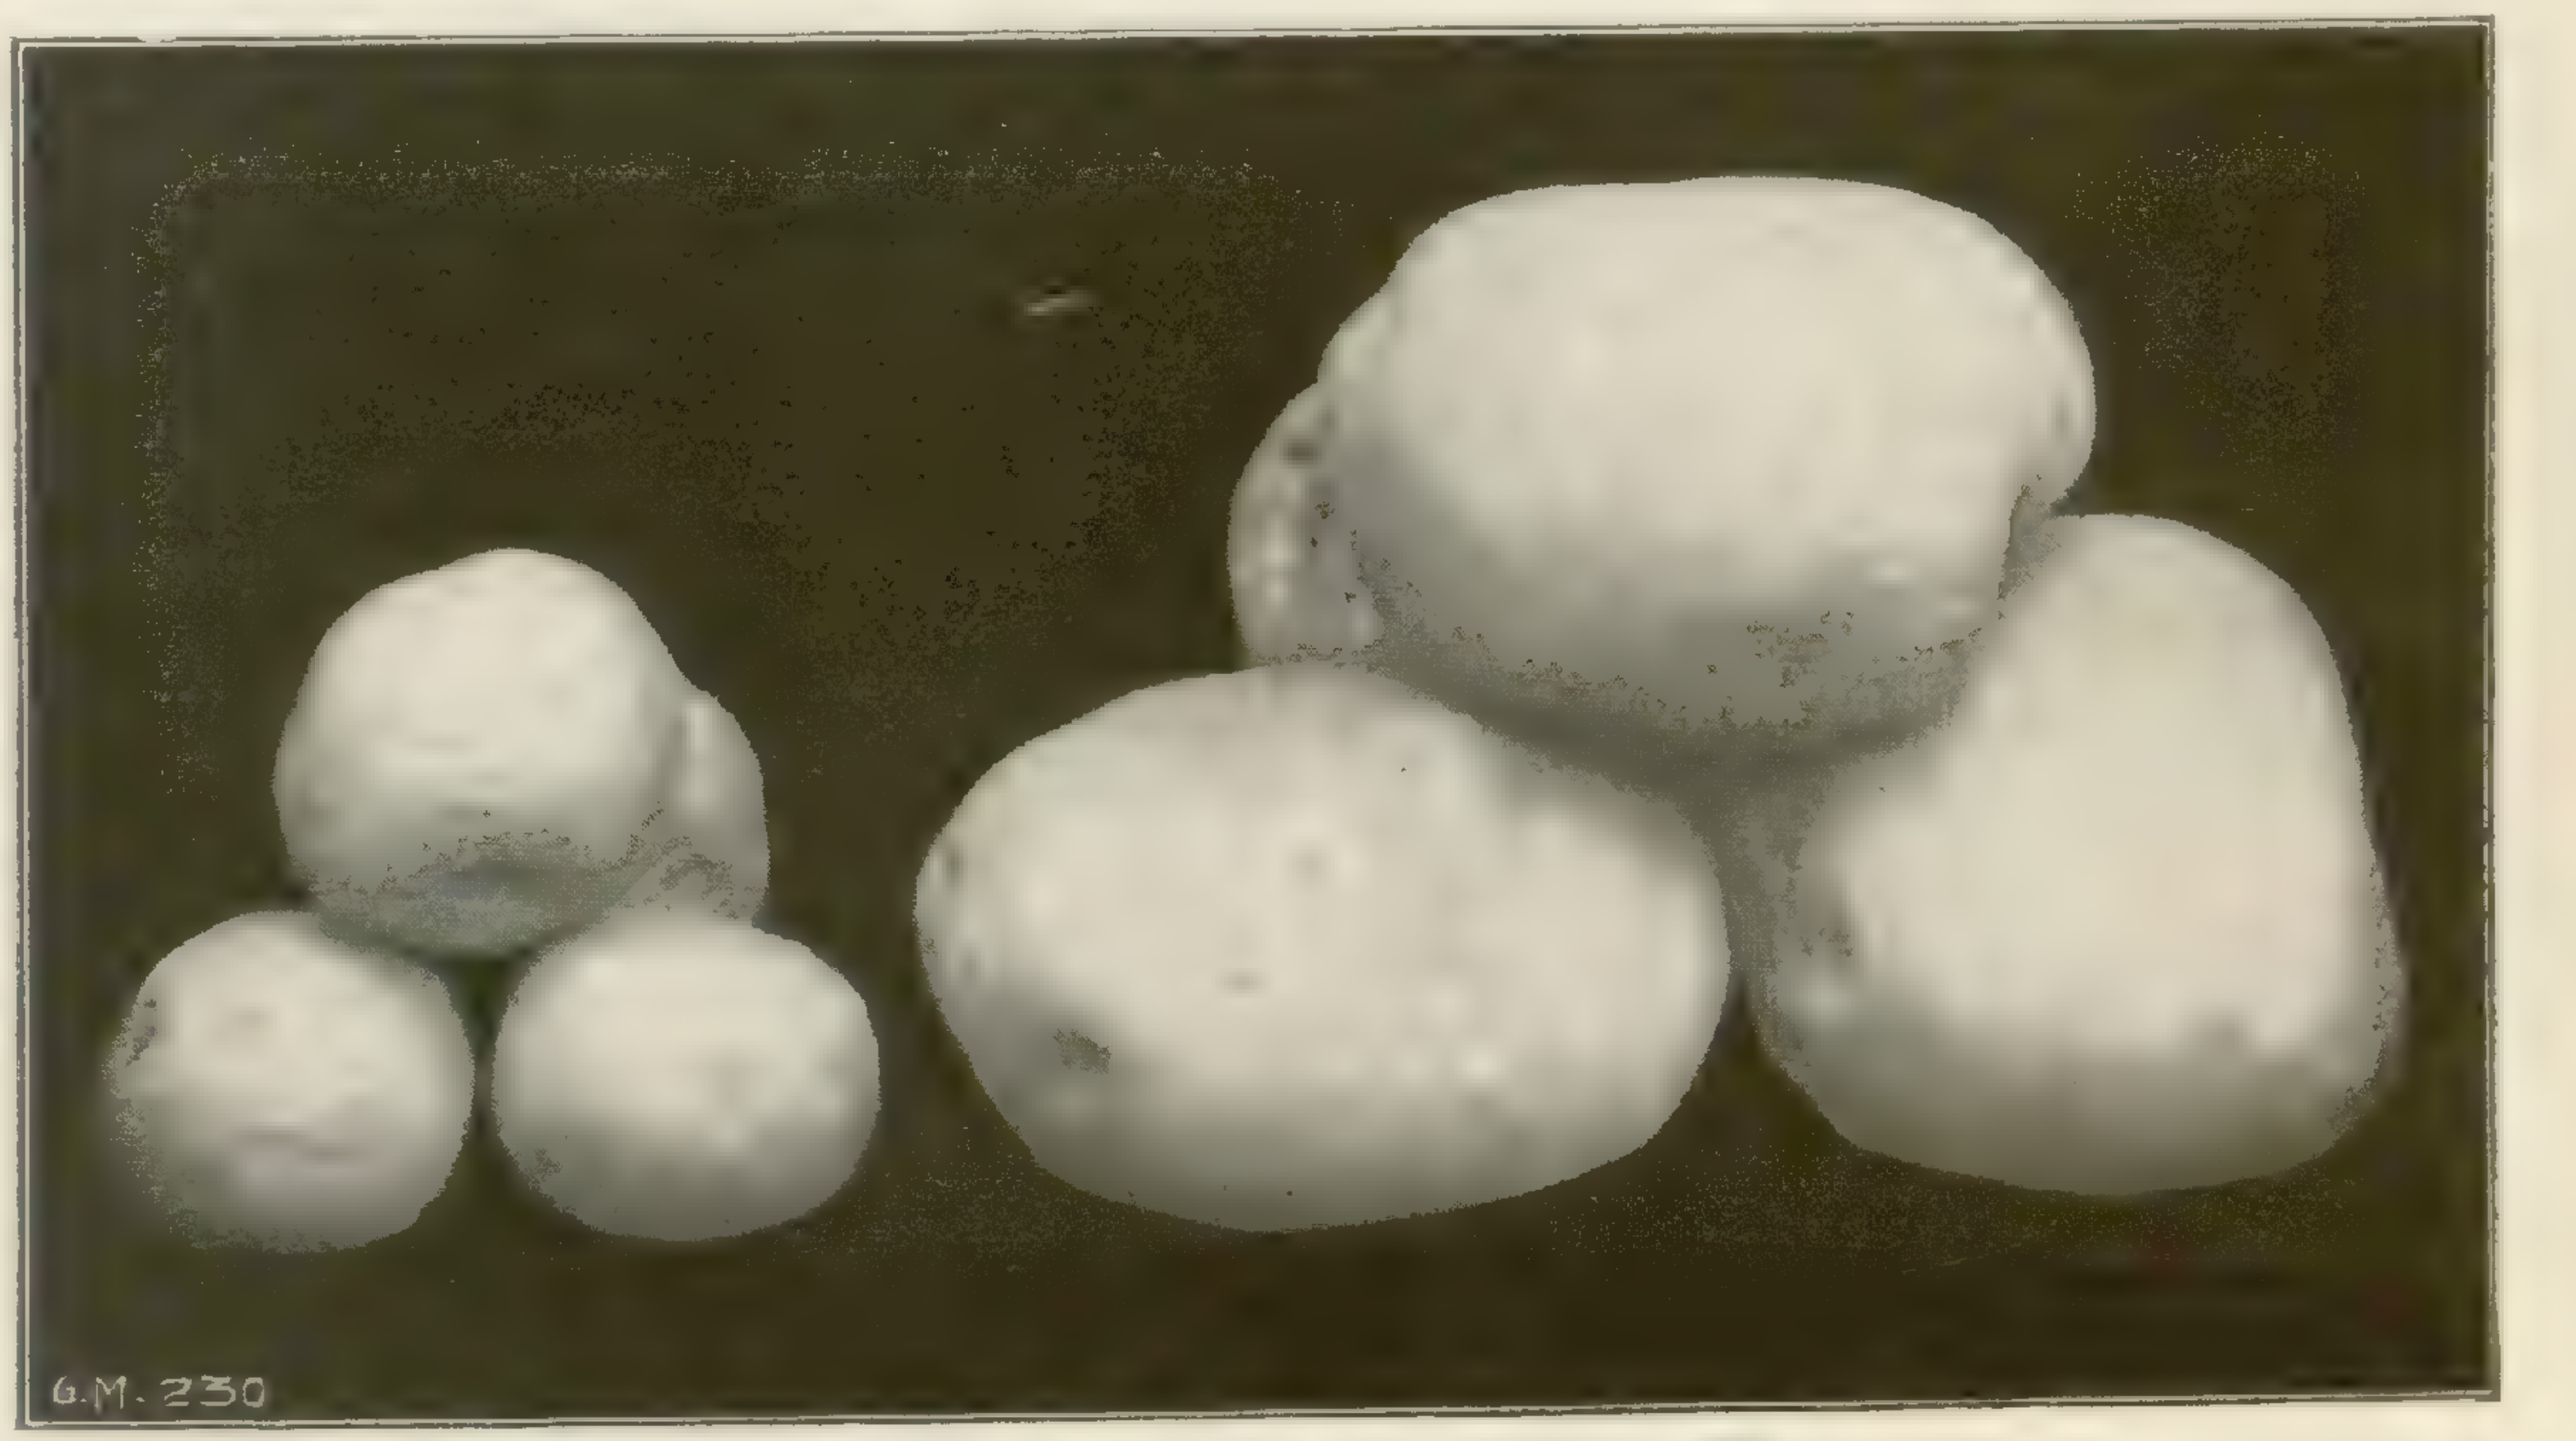
Solanum, a wild species from Mexico.

Solanum Ohrondi (?) (Carrière).

Potato — "Solanum Commersoni violet" (Labergerie).

Seedlings from "Solanum Commersoni violet" (Labergerie).

Hybrid-Seedling — "Solanum Commersoni violet" (Labergerie), x Solanum Commersoni (Dunal) (flowers white).



SOLANUM ETUBEROSUM, AS EXHIBITED BY MESSRS. SUTTON AND SONS.

A.—Tubers as originally received.
B.—Tubers after twenty years cultivation, except that these are often relatively twice as large.

Potato—Blue Giant (Paulsen).

Seedlings from Blue Giant (Paulsen).

A South African Potato, No. 3.

Seedlings from South African Potato, No. 3.

A South African Potato, No. 1.

A South African Potato, No. 2.

A Chilian Potato, No. 1.

A Chilian Potato, No .2.

(Several of the wild types named above were shown in growth.)

Whether we are within measurable distance of settling the question of the original type from whence the potato of Commerce has arisen it is, perhaps, too early to say with certainty, but such a collection of wild forms provides great possibilities in research work of this kind, and we understand that some extremely interesting facts have been brought to light during the past year or two which will, we hope, encourage Messrs. Sutton to continue their enquiries.

There is no better guide to the kitchen garden than Vegetables and Their Cultivation, by T. W. Sanders. It is a complete treatise on the general management of the garden, and the successful culture of vegetables, saladings, and herbs for home use. Price 5s. net, by post, in box, 5s. 6d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEASONABLE REMARKS.—With the sun daily gaining more power shading must have consideration. The blinds should now be put into working order, and they will thus be ready for use when required. In the cool house and for newly-potted plants one has to be particularly careful to observe the angle at which the sun's rays reach the foliage of the plants, so that the blinds may be brought into use at any moment during the hottest part of the day, or at any time when there is a danger of scorching. For cool house orchids, and where large growths and pseudo-bulbs are obtained, I find with the greater amount of root space and moisture-retaining compost afforded that the plants, when properly established, will stand more light than was the case with shallow potting. I mention this particularly here, to illustrate the necessity of proper discretion being used as to when shading is necessary, and to see that it is removed as soon as it can be dispensed with.

VENTILATION.—The methods of admitting air to our houses are pretty generally understood, but one or two observations may be of service. It is all very well to advise ample ventilation when the outside conditions permit, but these conditions are often misunderstood, or at any rate carelessly acted upon, even with an outside thermometer at hand, which may be consulted. Even with bright sunshine at this season of the year, there is always a chilling briskness in the atmosphere, and thus we have two factors to guard against—the sun raising the temperature to an undesirable degree, and the admission of cold draughts. No hard and fast rules can be laid down, and one can only expect that those in charge of the houses must use discretion in such matters. Another item I might mention in respect to ventilation; it is the desirability of avoiding checks unfavourable to young and tender growth. It is only natural that when the sun has been shining on the houses for some hours before the blinds are brought into use, the temperature will have risen so much that a considerable amount of ventilation has been brought into use. Bringing the blinds into use immediately reduces the temperature inside the house, and where lath roller blinds are used the fall is exceedingly rapid. This is where the observant and careful cultivator will be found on the alert, and will immediately reduce the ventilation, so that any chilling effects likely to occur may be counteracted to a great extent.

DAMPING DOWN.—Affording moisture by wetting the floor, staging, etc., must now also have careful consideration. There are many plants in a more or less active state of growth, and needing encouragement, and the moisture in the atmosphere of our houses is one of the chief factors in assisting renewed vitality. Our aim must therefore be to provide, as far as possible, suitable conditions for development. The outside conditions must govern the amount of atmospheric moisture we may safely afford. The greatest difficulties are perhaps experienced during prolonged mild and dull weather; but with a discreet use of artificial heat and ventilation these may be counteracted.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CLIVIA MINIATA.—No collection of greenhouse plants can be considered complete that does not include a few clivias. Amongst the most easily grown of all indoor plants these are also among the most brilliantly coloured of those that flower early in spring. The large trusses are now rapidly expanding, and the flowers, of a brilliant orange-scarlet, provide a colour of which there is at this season no exact counterpart. Clivias are free-rooting, robust subjects, and now, when the flower spikes are pushing, occasional supplies of liquid manure are beneficial. The potting material should be rich loam, leaf-soil, and silver sand, but care should be taken not to overpot the plants. It is not so much the amount of roots as the proportionate size of pot and plant that must be considered. During autumn the plants should be kept rather dry, as this checks leaf growth, and aids in the formation of the flower trusses. Clivias may be grown and flowered in an ordinary vinery or greenhouse, but prefer a slightly warmer place.

CLEMATIS INDIVISA LOBATA.—This pretty greenhouse climber is now coming into bloom. The pure white star-like flowers, which are produced in long racemes, are very effective. As it blooms at a season when few greenhouse climbers make much show it is all the more desirable, and no collection of greenhouse plants should be without it.

MAIDENHAIR FERNS FOR CUTTING.—Plants of the Maidenhair Fern, Adiantum cuneatum, should now be examined. Unless the supply of cut fronds is required at one particular time of the year only it is needful to have a succession, for to use the same plants throughout the season does not answer, at least not in private establishments. If the stock is now mixed, it can easily be separated. Some will be starting away into growth much earlier than others, and these may be made the earliest; continuing the process of selection, it will be easy to thus make at least three batches. The earliest one should be encouraged to make its growth as quickly as possible, so as to be ready for cutting in good time. However, strong heat and any great amount of moisture are not desirable, neither the one nor the other being productive of hard enduring fronds. One of the best places now would be a vinery, where the vines are just breaking, or a peach house in which the fruit is about set, a shelf in either instance being the preferable position. Those plants forming the second and third batches should for the present be kept cool, the later ones receiving scarcely any water for a few weeks longer. Of course, to expose such plants to sunlight and air would not be advisable. Neither of these later lots need have so much heat as the first. The latest will, in all probability, start kindly in a close frame without any heat to excite them.

IRIS RETICULATA. — This charming little iris is also well adapted for pots, and amateurs who have nothing but an ordinary greenhouse can have it in flower very early in the year by potting the bulbs in autumn, removing them under glass, or covering them with leaf-mould to the depth of three or four inches, and taking them into the greenhouse as soon as half an inch of growth has been made. Much heat ruins it. It does not even care for an intermediate house, but comes on rapidly and strongly in a temperature of from 40 to 45 degrees at night. The blooms last some time in full beauty, and look charming when cut and arranged in small glasses with some of their own foliage.—T. B. FIELD, Ashwellthorpe, Norwich.

THE FLOWER GARDEN.

ALL CLIMBERS on walls, pergolas, arches, etc., should at once be pruned and tied in. Ampelopsis should have all loose branches cut away, unless there is room for laying them in, when they should be neatly secured to walls. Wistarias should be extended where there is room, and have other growths pruned back to two or three good flowering buds from the old wood. Planting may still be done, but complete it as soon as possible. Clipping or cutting ivy may be left until next month.

ROCKERY.—Planting should now be completed; planting in masses has a much better effect than single plants, due regard for each kind being given. Arabis, alyssum, iberis, etc., must be planted nearer the summit than primulas, cardamines, prunellas, acænas, and helianthemums. Ramondia pyrenaica should be planted in the clefts of rocks, where colonies of them are very pleasing. Saxifraga Wallacei should have a favourable position in every rockery, and on the summit some of the taller-growing plants and shrubs, such as Rubus phœnicolasius, Wichuraiana roses, broom, gorse, cistus, kniphofias, and arundos (in good soil), etc., should be placed. The little Bambusa pygmæa is well suited for rambling in the lower parts, and if the position is favourable it will spread rapidly. See that the rockery is well cleaned all through, and any necessary top-dressing given before growth begins.

HERBACEOUS BORDERS.—All planting should now be finished as growth is starting. As the eremurus appear above ground it is advisable to cover them with nine or more inches of leaf-soil, to protect them from severe late frosts. Hepaticas and the earlier bulbs are now showing more and more of their beauty. Kniphofias may now be divided and replanted, but avoid severing more of the roots than is absolutely necessary. Carefully disentangle the roots, and plant in well-prepared, good, deep soil, but not in a waterlogged one.

SEEDS of matricarias, larkspurs, salpiglossis, alonsoa, petunias, nicotianas, coreopsis, annual chrysanthemums, etc., etc., may now be sown in gentle heat; do not sow seeds thickly or place in too strong heat, sturdy vigorous growth from its earliest stages being much the best. Continue to prick off seedlings from previous sowings. Kochia scoparia is among the most beautiful of the narrow-leaved ornamental foliage plants for warm districts; unfortunately I do not find it a success here, as it does not assume its proper autumn colour.

CANNAS may now be divided and started in gentle heat; use the outside growths of clumps, and not inside ones, as these do not readily start into growth.

PROPAGATING.—Continue to propagate fuchsias, salvias, heliotropes, ageratums, cupheas, coleus, lobelias, etc., cuttings of these should be inserted as recommended in previous notes, and where carpet or pattern bedding is still practised, alternanthera and other cuttings may now be inserted. Autumn-struck zonal pelargoniums should be potted and grown on in a genial, but not high temperature, giving all the light possible except for a few days immediately after potting, though where they were struck singly in small pots this does not apply.

STANDARD PLANTS of fuchsias, heliotropes, plumbagos, etc., should be carefully cut back, cleaned over, and started in gentle heat. Where a young batch is to be grown up a start may now be made; select the varieties and plants most suitable, and grow to a single stem until the desired height is reached, when they must be pinched or stopped.—E. F. HAZELTON, Knowsley Gardens.

HARDY FRUITS.

PEACH AND NECTARINE TREES.—In some gardens, where the trees are not numerous, pruning and nailing is left till rather late, but where there is a deal to be done the work must be taken in hand at once and completed before the buds are too forward. If the trees were well attended to last summer in the matter of disbudding and carefully selecting suitable shoots for fruiting this season, very little pruning should be required at the present time. In the case of neglected trees, it will be well to take from the walls all the branches, cut out those not required, and train in younger wood. See that all the main branches are as evenly balanced as possible, so as to give the individual tree a good appearance. Young shoots should then be neatly secured to the walls or wires as straight from the base as possible. Do not use too many nails, be careful not to injure the bark when driving the nails into the walls, and allow plenty of space between the nail heads and the wood, otherwise much harm may be done to the bark. Finish with a good syringing with soapsuds to cleanse the trees of insect pests. Young trees may now be put into order. If planted before December the soil will by this have become settled; but to be on the safe side, before nailing the branches to the walls give the soil a good trampling. All peach trees should have ample room for development, and the young shoots must be kept thinly placed.

APRICOTS.—These being amongst the first of hardy fruits to bloom, the flowers are very liable to become damaged by frost, and considering that the buds are plumping up fast no time should be lost in putting the trees into good order. If the spurs are numerous and long some may be removed to give the others a better chance. Secure the young wood neatly at intervals all over the trees, as this will, in a couple of years give the best fruits, and will also serve to fill up any gap which may take place at any time. In some gardens the apricot seems to thrive well, producing fine fruits annually, the wood and trees generally being a picture of health. But in other gardens no sooner is a good tree formed than gumming sets in and destroys some of the best-placed branches. Good fibrous loam, well drained, with plenty of chalk and old mortar, is the most suitable soil for apricots. See that all the protecting material is made in readiness for use as soon as there is danger of damage to the buds by frost.

ALPINE STRAWBERRIES.—These may be increased by runners, divisions, and from seed. Seed may be sown in well-drained pans at the present time; the pans should be clean, dry, and filled with sandy soil, sweet and fresh. Cover the seed thinly with fine soil, and place the pan in a gentle warmth, covering it with a square of glass and brown paper till the seed begins to germinate. If the soil is fairly moist at the time of sowing no water will be required for some time, and when water is given every care should be taken not to wash the seed bare. In fact, after each watering, and until the plants are nicely up a sprinkling of sand over the surface will be an advantage. Prick the seedlings off when large enough, and encourage them to grow, first in pans, and then in boxes. The plants may then be gradually hardened, and finally planted out in June on a well-prepared piece of land made firm. These plants do not require a too rich soil, and should be allowed about twelve inches between the rows and the same distance from plant to plant. See that a good strain is obtained from some good firm.—H. MARKHAM, Wrotham Park Gardens.

EXHIBITIONS AND MEETINGS.

◆

Royal Gardeners' Orphan Fund.

FEBRUARY 14.

On the occasion of the annual meeting of this excellent charity at Simpson's, Strand. Mr. H. B. May, chairman of committee, presided over a small number of members. The number of members present was probably smaller than at any of the annual gatherings since the origination of the fund, and was no doubt due to the satisfaction of the members with which the committee and officers discharge their respective duties. The notice convening the meeting, and the minutes of the previous annual meeting having been read by Mr. B. Wynne, the secretary, it was decided to take the report and financial statement for the past year as read.

REPORT AND FINANCIAL STATEMENT.

The following is the report, in a somewhat abbreviated form, presented by the committee: In presenting their twentieth annual report, which practically brings the official record of the operations of the fund since its establishment up to its twenty-first birthday, the committee most heartily congratulates all past and present supporters on another year of steady progress and increasing prosperity and usefulness, and on a record of good work accomplished during the twenty years of the existence of the fund, such as none could have anticipated, who, in the early months of 1887, took part in laying its foundation.

At the end of the first year a very modest start was made with the election of eight candidates at a cost of £139 15s. At the end of 1907, the number of children in receipt of the full allowance, granted after election, was 95, while nineteen others were receiving much-needed financial assistance while waiting for advancement to the full pay list, the total amount distributed during the year being £1,511 10s., or £100 more than the previous year's total. At the commencement of 1907, there were 95 children receiving the full allowance, and nineteen were added to the list at the annual meeting in February, bringing up the total number of orphans elected during the twenty years to two hundred and thirty-six, while the total sum expended in allowances and grants in aid during the same period amounted to no less a sum than £17,884 12s. 6d. The total amount of the receipts from all sources up to the end of 1907 is £36,884, to which, besides providing the large sum distributed in accordance with the objects for which the fund was established, has enabled the committee to provide a reserve fund of over £11,000, all well invested, and the dividends accruing from which more than provide for all necessary working expenses.

As regards the accounts of the past year, which show an increase in receipts over 1906 amounting to £69 18s. 10d., an increase of £100 in the children's allowances, an addition of £120 16s. 11d. to the amount invested in Consols, an addition of £50 to the deposit account, and a larger sum carried forward; the committee have again to deplore the one weak spot, i.e., the comparatively small sum received in the form of annual subscriptions, and once more most earnestly appeals for a larger measure of support under this heading.

Under the genial, and so happily appropriate, presidency of "the children's Lord Mayor," Alderman Sir William P. Treloar, Bart., the annual festival dinner held at De Keyser's Royal Hotel, E.C., on May 23, was again both socially and financially an unqualified success, the chairman's list for the second time in the history of the fund exceeding £1,000, while the attendance of friends and visitors was also larger than heretofore.

With the utmost possible satisfaction the committee make the announcement that in order to fittingly celebrate the coming-of-age of the fund, the noble president, the Duke of Bedford, K.G., has most kindly consented to preside at the forthcoming festival, which has been arranged to take place at the Hotel Cecil on Tuesday, May 12, when it is earnestly hoped that all friends and supporters will unite with the committee in their efforts to render the festival worthy of such an auspicious occasion.

The warmest thanks of the committee are again most heartily accorded to all who have assisted in promoting the welfare of the fund during the past year, and especially is grateful acknowledgment due to the Right Hon. Mary, Countess of Ilchester, Sir Frank Crisp, and Major John W. Dent, for so kindly opening their private gardens to the public, in aid of the charity, to the stewards at the annual dinner, the honorary local secretaries, and the many good friends in such centres as Altrincham, Chesterfield, Bradford, Reigate, Chislehurst, etc., who have again sent up most acceptable contributions.

With very sincere regret the committee records the fact that the fund has suffered grievous losses during the year by the lamented deaths of so many constant and valued supporters. From the role of vice-presidents the names of Lord Battersea and Dr. Maxwell T. Masters, F.R.S., will be greatly missed. Lord Battersea will be specially remembered for his graceful advocacy of the claims of the charity to the support of all lovers of horticulture at the annual dinner in 1900, while Dr. Masters from the inception of the fund had wholeheartedly supported it in every way, and specially rendered most valuable assistance in the drafting of the rules which, largely owing to his sagacious counsel, have since been found to work so smoothly. Very deeply indeed do his old colleagues deplore the loss of Mr. John Assbee, who for nineteen years was one of the most regular attendants at the meetings of the committee, and an enthusiastic and sympathetic worker.

During the year the committee has again been much gratified by the generous assistance rendered to the fund and the keen interest taken in its management by the treasurer, Mr. Edward Sherwood, who is hereby most gratefully thanked, and very cordially nominated for re-election.

The members of the committee who retire by rotation are Mr. W. R. Alderson, Mr. George H. Barr, Mr. George H. Cuthbert, Mr. William Howe, Mr. John Lyne, Mr. William Poupart, Mr. Thomas W. Sanders, and Mr. William P. Thomson, and, all being eligible, offer themselves for re-election. For the vacancy created by the death of Mr. Assbee, the committee has great pleasure in recommending the election of Mr. Edward Parsons, of Messrs. Parsons and Co., Lim., Fruit Market, Covent Garden, a gentleman who for some years past has been a generous supporter of the charity, and a regular attendant at the annual festivals.

The auditors, Mr. M. Rowan and Mr. P. Rudolph Barr, are again most cordially thanked for the carefulness with which they have made the annual examination of the accounts, a duty most cheerfully rendered, though annually making a greater demand upon their time owing to the steady growth of the institution.

The Chairman, in moving the adoption of the report and financial statement, said it would not be necessary for him to speak otherwise than briefly, for the past year had been rather uneventful. The fund had received the same generous support as in previous years, and had been able to give substantial and much-appreciated assistance to a large number of the orphans of gardeners and others engaged in horticultural pursuits. There had also been the same unanimity and devotion to the interests of the fund by the members of the executive, which had so largely contributed to the splendid success that had been received. Reference was also made to the development of the charity during the past twenty years, and to the losses from death that had been sustained during the past year. As evidence of the value of the assistance rendered by the charity to orphans, the Chairman read a letter from a lady subscriber, who has taken a keen interest in two children who are participating in the benefits of the fund. He also read an interesting letter from Mr. H. J. Clayton, late of Grimston Park Gardens, who, in 1887, made, with Mr. J. Udale and the late Charles Penny, a proposal that a fund for the support of gardeners' orphans should be founded as a memorial of Queen Victoria's reign.

In the course of his letter, Mr. Clayton wrote:

"It was extremely fortunate that the germ fell upon such good soil, which, being diligently tilled and tended, has brought forth results which none of those who helped to set the fund upon its feet could have believed possible. Still, great as the success of the fund has been, and so able its management, I think more might have been done to nourish and strengthen it by my brother horticulturists of all grades. The annual subscription of five shillings means only a trifle over a penny per week, and such a sum surely cannot be much of a burden to the many who have not hitherto helped in the good cause. To want of thought rather than to want of heart, must, I think, be attributed their lack of interest in our institution, the objects of which should appeal to all.

"In the letter to which I have referred, I remarked that while there may be some who are opposed on principle, I venture to think wrongly, to the granting of pensions to old or disabled horticulturists, there are surely none so stony-hearted as to grudge or refuse to help unfortunate children in need of food and guidance. I think so still.

"I trust I may not be considered presumptuous if I make the suggestion to your committee, and beg for it their most favourable consideration, that advantage should be taken of the twenty-first birthday celebration to organise a poular shilling collection among all classes of workers in horticulture, with a view to obtaining a handsome birthday present with which to head the noble chairman's list. Taking them in the bulk at, say, 10,000, am I too sanguine in thinking that as many shillings could be obtained if only there is the will to make the effort to collect them? Think what a grand gift it would be to the charity—and to be obtained at such a trifling individual cost to the contributors. The fact that the noble president, the Duke of Bedford, is to take the chair on May 14, and the knowledge so obvious to all that the fund has been admirably managed in the past, and is now so firmly established on a sound financial basis, should be a strong incentive to effort in the direction I have indicated.

"I do not venture to make any suggestion as to how such a special collection should be organised; I hope only that the committee may be disposed to try it, as I feel sure that if they will, and the gardening papers will give it their blessing and support, the secretary will know how to deal with the matter, and—I hope and trust—make it a success if at all possible.

"With every good wish for the continued prosperity of the fund in every way, and that God's blessing may rest upon the good work."

Mr. William Marshall, V.M.H., seconded the motion, and, in the course of his remarks, congratulated the committee on the splendid financial results of the past year. On being put to the meeting, the motion was unanimously adopted.

On proceeding to the election of officers and committee, Sir W. Treloar, Bart., was elected a vice-president, Mr. Edward Sherwood was re-elected treasurer, Mr. Rowan re-elected auditor, Messrs. W. R. Alderson, G. H. Barr, G. H. Cuthbert, W. Howe, J. Lyne, W. Poupart, and T. W. Sanders, were re-elected members of committee. Mr. Parson was elected a member of committee to fill the vacancy caused by the death of Mr. Assbee; and Mr. B. Wynne was re-elected secretary. The several motions were made or seconded by Messrs. W. Poupart, Bull, Lyne, Roupell, Castleton, Gordon, Dean, McLeod, Ingamells, W. Cutbush, Bates, and the Chairman.

The meeting was then adjourned until 4.30 p.m., the time fixed for closing the poll. On reassembling, Mr. W. Poupart reported the results of the ballot as follows: P. E. S. Warwick, 377; Lucy M. Claxton, 367; Alice Arnold, 361; Herbert E. Smithers, 358; Jeanie M. Lamond, 353; John M. McCullum, 322; Edward J. Ward, 294; Hilda E. Tickner, 257; Bessie Seaman, 221; Thomas H. Thomas, 182; Ethel M. Blackmore, 133; Dorothy Wiggins, 130; William H. N. Mullens, 127; Violet G. Randall, 102; Algie R. Gascoigne, 71; Reginald G. Grist, 64; and Ellen Ashton, 60. The Chairman then declared the thirteen candidates who obtained the largest number of votes duly elected, and, on the motion of Mr. George Gordon, a vote of thanks was accorded the scrutineers for their services.

Mr. H. J. Veitch, V.M.H., said, in view of the fact that the fund had entered on the twenty-first year of its useful work, he would like to suggest that the four unsuccessful candidates be elected to the benefits of the fund. On the Chairman having intimated that if it was the wish of the meeting that this should be done, the committee would not raise any objection. Mr. Veitch then formally moved a resolution in accordance with his suggestion, and this having been seconded by Mr. T. W. Sanders, was carried unanimously.

On the motion of Mr. H. J. Veitch, a vote of thanks was accorded the chairman.

In the evening the officers and members of committee with a few friends dined together at Simpson's, and this brought a pleasant day's work to a close.

National Chrysanthemum Society.

A well-attended committee meeting was held at Carr's Restaurant, Strand, W.C., on Monday, February 17, Mr. T. Bevan presiding. Sir Albert Rollit, the new president, was present, and he brought up the question of holding exhibitions in London, and asked the members to carefully consider the fact that membership had fallen during recent years, and why this was so, and to endeavour to find methods of retaining and increasing membership.

Barry and Newcastle Societies were admitted to affiliation, and several new members were elected. A budget for 1908 was submitted by the secretary, and this showed receipts amounting to £492 12s., and expenses £444 12s., leaving an estimated balance of £27, or really of only £2, allowing for the replacement of £25 to the reserve fund. The estimates were agreed upon, and the schedules of the 1908 shows were passed; the prizes offered at the October show will amount to £56 9s.; November show, £288 3s.; December show, £46 8s. The election of members to the Floral Committee resulted in the re-election of Mr. C. H. Curtis (22), Mr. G. Prickett (22), Mr. F. G. Oliver (21), and Mr. W. Higgs (18), and the election of Mr. R. Felton, Mr. Springthorpe, and Mr. Gilks to fill vacancies arising.

Messrs. P. Cragg, D. Ingamells, and J. W. Moorman were re-elected, with the officers, to form the Finance Committee. Messrs. C. H. Curtis, P. Cragg, D. B. Crane, W. Howe, D. Ingamells, E. Jones, J. W. Moorman, F. G. Oliver, and E. Prickett were re-elected as the Schedule Revision Sub-committee, and Messrs. C. H. Curtis, D. B. Crane, A. Foster, D. Ingamells, and E. Jones were re-elected to form the Publications Committee, though their duties will probably be very small this year.

The question of a summer outing was discussed, and July 27 was considered to be about the best date for it; the matter was left in the hands of the officers.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE.

Present: Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Rev. W. Wilks, Dr. M. C. Cooke, Dr. A. B. Rendle, Professor G. S. Boulger, F. D. Godman, W. B. Hemsley, H. T. Güssow, W. C. Worsdell, A. W. Sutton, W. Hales, L. H. de B. Crawshay, G. S. Saunders, H. J. Elwes, J. T. Bennett-Poë, C. T. Druery, G. Gordon, W. Cuthbertson, J. Douglas, and F. J. Chittenden (secretary).

RED CURRANT TWIGS TWISTED.—Mr. H. T. Güssow showed shoots of red currant twisted and curled at the tips, arising from the confinement of the young growths under nets.

MICROLOMA LINEARE.—Mr. J. O'Brien sent specimens of this uncommon asclepiad, showing how it climbs over bushes in its native home in South Africa. The plant was figured some time ago, but is very rare in cultivation.

BIGENERIC ORCHID HYBRID.—Sir Jeremiah Colman showed a hybrid raised between Diacrium bi-cornutum and Cattleya intermedia nivea. The colour of the diacrium had been almost entirely lost except for a tinge of sulphur in the labellum. The parent species are usually regarded as being widely separated in natural relationship, but a hybrid between D. bi-cornutum and Lælia cinnabarina was awarded a botanical certificate on March 14, 1905.

NOMENCLATURE OF HYBRID ORCHIDS, ETC.—Some discussion took place place with regard to the naming of hybrids between species assigned to two or more genera. The general opinion was that such hybrids should, when raised between plants belonging to two different genera, have the names of both genera indicated; but where the progeny was the result of crossing a bigeneric hybrid with a plant of another genus altogether, a purely conventional name should be assigned, preferably with a distinctive termination. The further discussion of the matter was adjourned to another meeting.

DISEASED SWEET WILLIAMS.—Lady Hopkins, of Romsey, sent sweet williams in a dying condition with pale brown spots upon their leaves, which were due to the attacks of the fungus Puccinia dianthi. This fungus frequently proves fatal to the sweet william, and the infection is said to be carried in the seed, so that whole batches are killed. The particular variety in the present case was Pink Beauty, and the present is the second year in which the trouble has occurred, though in different spots in the same garden.

INSECTS ON OLEANDER, ETC.—Mr. G. S. Saunders reported that he had examined the insects found upon various plants in a greenhouse, and sent by Mr. Stanton Brown, A.R.H.S. They belonged to the family Psocideæ, and were specimens of the uncommon species Cæcilius Dali. This species is not known as a plant pest, but is said to feed upon fungoid matter of various kinds, mould on palings and rust fungi on leaves, etc. It is most frequent upon the bark of trees.

Maidenhead Chrysanthemum Society.

The tenth annual general meeting of this society was held in the small Town Hall on Thursday evening, the 13th inst., and there was a good attendance of members and others. Mr. D. Ingamells, vice-chairman, presided. The report and balance-sheet were most satisfactory. The entries in local classes were thirty-seven in advance of the number in the previous year. The competition in the amateur and cottagers' classes was also much better. The show was, in fact, a great success, and the balance in hand is £16 13s. 10d. The Right Hon. Lord Boston was re-elected president; C. de M. Caulfeild Pratt, Esq., was re-elected chairman; Mr. D. Ingamells, vice-chairman; Mr. George Mattingley, treasurer, and Mr. J. W. Richardson, hon. secretary. The exhibition is fixed for Thursday and Friday, October 29 and 30, and will be held in the Drill Hall, Maidenhead.

East Anglian Horticultural Club.

There was a very large gathering of members at the February meeting of this club held at the Boar's Head Hotel, Norwich. It had been arranged that an interchange of lectures should take place between this club and the Ipswich Gardeners' Association, and as an outcome Mr. W. Messenger, The Gardens, Woolverston Park, came along and gave a most practical and interesting paper upon "Wall Fruits." The subject was dealt with in every phase and detail, from the preparation of soil and building of walls to the storing and subsequent placing of the fruit upon the table. His points upon planting, pruning, and treatment of pests were most carefully explained. The paper throughout was most understandable, and even the most uninitiated present could not go away having learnt something. A most interesting discussion followed, Mr. L. Smith, Shotesham Park Gardens, and Mr. H. Goude, The Grange Gardens, Catton, adding some interesting local points of culture. Other debaters were Messrs. T. B. Field, E. Peake, J. C. Abel, J. Powley, and H. Perry.

The exhibits did credit for so early a date. Mr. W. Shoesmith, gardener to F. W. Harmer, Esq., Cringleford, staged some splendid bulbous and other plants, and choice apples and pears. Mr. F. Williams, gardener to Louis Tillett, Esq., M.P., had some choice exhibits, the most noteworthy being a grand pot of Tulip Kreizers Kroon. The stewing pears and cooking apples staged by Mr. G. Moore, Hethersett Hall Gardens, were splendidly plump, showing great care in storing. Other exhibits came from Messrs. C. H. Fox (Catton), C. Hines (Trowse), C. Burtenshaw (Norwich), E. Grand (Cringleford), and W. Laws. Mr. T. B. Field brought up from Ashwellthorpe a bunch of Winter Sweet (Chimonanthus fragrans), which was very charming, the individual flowers were very large, and were quite attractive by reason of their delicious perfume.

British Gardeners' Association.

The monthly meeting of this association was held on February 11, at the R.H.S. Hall, Westminster, Mr. Charles Foster in the chair. Twenty-four new members were elected, bringing the total up to 1,163. The secretary submitted a detailed statement estimating the receipts and expenses of a monthly "Journal." The question was thoroughly discussed, and it was decided by eight votes to three that a monthly "Journal" should be established in April, after the next issue of the present quarterly.

A request to hold a meeting for the benefit of gardeners employed in the London parks having been received, it was decided that one be held at Carr's Restaurant, on Saturday, March 7, at seven p.m., and the secretary was deputed to give an address on that occasion.

It was also decided to send a delegate to address a meeting at the Wesleyan School, Evelyn Road, Richmond, Surrey, on Tuesday, February 25, at eight p.m., when Mr. Hawes will be in the chair. The secretary was instructed to procure a die for the new certificate.

Sandhurst Gardeners' Association.

The usual meeting was held on February 14, and there was a large attendance of members, presided over by Mr. J. Evans. The paper read was on "Herbaceous Plants," by Mr. L. T. Petty, of The Gardens, Tylney Hall, Winchfield, who showed he was well acquainted with his subject. The various modes of propagation, time of planting, watering, and general treatment of the various kinds of plants were all most fully dealt with, and a few notes were given concerning the newer introductions of hardy plants. A good discussion followed, which was sustained by Messrs. Townsend, Moyes, Chapman, Evans, C. W. Goddard, M. Goddard, and Gear. Mr. Petty was heartily thanked for his excellent paper.

Mr. Townsend, Sandhurst Lodge Gardens, staged some splendidly-flowered cyclamens; Mr. Chapman, Hilfield Gardens, Yateley, sent eupatoriums, and Mr. Dupond, Crowthorne Nurseries, showed lily of the valley.

Bristol Gardeners' Association.

The usual fortnightly meeting was held on Thursday, February 13, at St. John's Parish Rooms. Mr. J. C. House presided over a very good attendance. Mr. Baily, representative of the Reading Society, introduced the subject of "Budding and Grafting," giving a short paper upon each that was full of interesting matter.

The lecturer then gave a practical demonstration fully proving his knowledge of these operations, and brief explanatory remarks while working, and he afterwards handed round the examples of his work. The best stocks to work, the various modes of grafting for different purposes, were each taken in turn and graphically described. Grafting by approach, rind, cleft, saddle, half-saddle, wedge, and tongue grafting, for fruit, forest, and ornamental trees; these were the modes and subjects dealt with, the lecturer keeping the audience exploding with hilarity at his witticisms. Mr. Baily was deluged with questions, the answers to which were equally as instructive as the lecture, and richly earned for him the hearty vote of thanks at the close.

For two cyclamen the first prize was awarded to Edgar Watts, Esq., The Priory (gardener, H. Woodward); the second to Alderman Howell Davis, M.P. (gardener, J. T. Curtis). There was only one exhibit of violets, the judges awarding first prize to the first-named for one bunch each of Princess of Wales and Marie Louise.

Commons and Footpaths Preservation Society.

At the monthly meeting of this society it was reported by Lord Eversley, who presided, that the society's Public Rights of Way Bill was set down for second reading for May 29, and that promises of support had been received from leading representatives of all parties. The main object of the Bill is to enable the provisions of the Prescription Act to be used in connection with the proof of highways and to simplify and cheapen litigation in footpath cases. It was decided to prepare a Bill to facilitate the regulation of rural commons, and Sir John Brunner consented to introduce the Bill on the society's behalf. It was pointed out that in many neighbourhoods commons formed the camping grounds of vagrants who could not be satisfactorily dealt with without bye-laws made under a regulation scheme, and it was felt by the society that the time had arrived when privileges of compulsory regulation similar to those enjoyed by the Metropolis since 1866, with proper safeguards of the rights of the lord of the manor and commoners, should be extended to the whole of the country. The solicitor reported that eleven railway and water Bills now before Parliament affected common lands and open spaces, the total area proposed to be absorbed exceeding 1,614 acres. Twenty-one other Bills affected commons and rights of way.

It was decided to press for the insertion in the Burnley Corporation, Monmouthshire County Council, and Pontypridd Waterworks Bills, under which large areas of common lands have been scheduled, of clauses to provide for the public right of access to the commons. It was also decided to support the local opposition to the Fishguard and Rosslare Railways and Harbours Bill, which seeks to absorb the whole of Goodwick Moor, and to oppose, if necessary, the London and Windsor Motor Roads, Tramroads, and Tramways Bill, which would involve serious injury to Ravenscourt Park, Stamford Brook, and Back Common, Chiswick, and other open spaces. The Secretary reported that the society was dealing with 120 cases of encroachment on commons or obstruction of rights of way, and that since the last meeting several footpaths had been reopened as a result of its efforts. It was decided to oppose a scheme for the enclosure of Coopers Hill Common, Gloucester, a beautiful open space, 136 acres in extent.

Shrubs.—Pruning should now be completed, and where there are no roots lightly fork the ground over, but avoid digging where there are roots. In the latter case give a dressing of short, well-decayed manure and leaf-soil, but do not place it quite close to the edge of the bed, or birds will probably soon scratch it over, causing an untidy appearance. From variegated shrubs cut away any green, badly-coloured, or erect growths that may appear. Such shrubs as Spiræa Douglasi, symphoricarpus, willows, Rosa rugosa, purple hazel, and others of similar habit are best cut quite down every year, or every alternate year.—E. F. HAZELTON.

Thunbergia laurifolia.—With reference to the note on Thunbergia laurifolia in the issue of the GARDENERS MAGAZINE for February 15, I am able, from personal experience, to inform your correspondent that Thunbergia laurifolia thrives with most satisfactory results planted in borders in the croton house. It gives a splendid display of flowers during January and February; the delicate colour of the flowers producing a pleasing effect. After flowering attention should be given to pruning, and the growths should be well cut back. To be successful in cultivation a rather rich soil is essential; a mixture of three parts of good loam to one of leaf-soil and one of well-decayed manure, with a liberal sprinkling of coarse sand and charcoal, being in every way suitable.—R. W., Sandringham.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

DODDER.—N. L., Keighley: The most important British Dodders are Cuscuta europæa, C. epilinum, C. epithymum, and C. trifoli, the latter being by far the greatest pest.

BEECH COCCUS.—M. M., Dorking: Spray the trees at once with the caustic soda and potash mixture, and give two other sprayings with the same kind of mixture, at intervals of three days.

BRITISH GARDENERS' ASSOCIATION. —Young Foreman: Mr. J. Weathers, Talbot Villa, Isleworth, is the secretary of this association, and he will give you the particulars you require. The annual subscription is 2s. 6d.

SNOWY FLY.—L. E. G., Hornsea: Fumigate or vaporise the house on calm evenings at intervals of a few days for a fortnight. Excessive heat has probably had something to do with the increase of the pest at this season of the year.

ADVERTISING.—N. C., Liverpool: The most complete list of horticultural societies and their secretaries with which we are acquainted is the one published in the "Gardening Year Book," to be obtained (1s. 2d. post free) from the GARDENERS' MAGAZINE office, 148, 149, Aldersgate Street, E.C.

LIFEBUOY SOAP FOR MILDEW ON ROSES.—L. E. B., Reading: We have no experience of the use of Lifebuoy soap as a preventive of mildew on roses, but we understand it has been so used, and with success. The proportions are half a bar of soap dissolved in three gallons of soft water.

DISEASES AND INSECT PESTS. — S. E. R., Ipswich: We can strongly recommend you to purchase "The Book of Garden Pests," by Mr. R. Hooper Pearson (2s. 6d., John Lane, Bodley Head). It is freely illustrated, and contains concise descriptions of insect and fungus pests, and remedies and preventives.

GRAFTING WAX.—A. F., Exmouth: For use either warm or cold an excellent grafting wax can be made by melting equal parts by weight of Burgundy pitch, kerosene wax, and tallow. Melt these together in an old saucepan, and mix well together. An old paint brush will serve to distribute the wax when warm, while a putty knife is a good tool to use when the wax is cold.

RUST OR MITE ON BEGONIAS.—F. F., Shepperton: The rusty appearance of the leaves is due to the presence of a mite that is so small as only to be detected by means of a microscope. The best remedy is that of dipping the affected plants in tobacco-water, to which a little soft soap has been added to make it adhesive. Dipping should be practised several times at intervals of about a week.

SPOTTED SYCAMORE LEAVES. — S. E. G., Wokingham: You should have sent us leaves for examination last autumn. So far as we can gather, the spots or blotches on the leaves were caused by a fungus named Rhytisma acerinum. These blotches appear yellowish at first, towards the end of June, and gradually grow darker until they are quite black at the end of the season. Infection is caused by allowing these diseased leaves to remain upon the ground where they fall, because the spores produced in spring from the black patches are those that spread the disease. Diseased leaves should be removed and burned as soon as they fall, and should on no account be allowed to remain, or be used for leaf-mould. Repeated attacks, if allowed to go unchecked, will enfeeble the tree, and permit it to fall a prey to one of the canker fungi.

ARTIFICIAL MANURE FOR ROSES.— C. C., Leicester: A good manure for roses growing in light soils that lack lime is made up by mixing up two parts of Peruvian Guano, one part each of bone-meal and dried blood, and a half part each of sulphate of potash and nitrate of soda. All these substances should be in as fine a state as possible, and be thoroughly mixed. Use at the rate of 5oz. per square yard early in spring, spreading the manure over the whole surface of the rose border, and not placing it in a ring or patch close to each plant. Hoe or rake the surface after applying the manure.

HARDY FERNS.—H. R. M., Matlock: We are glad to hear you have profited by the articles on hardy ferns that have appeared from time to time in our columns, and especially from those in which the desirability of selecting the finer varieties for planting has been emphasised. Your plan is an excellent one, and we can only suggest that to the staple you have to deal with a fair quantity of peat and leaf-mould should be added. These materials will render the soil warmer, and also lighten it, without making it excessively porous. We feel quite sure that choice hardy ferns are at last coming into popularity; indeed, with the advance of water gardening, rock gardening, and semi-wild gardening, that has been so marked during the last few years, it was inevitable that hardy ferns should be more largely grown. We have consistently taught that a choice variety is no more difficult to cultivate than a wild type, whereas its beauty and grace are incomparably greater.

GRUBS IN MUSCARI BULBS.—G. B., Yeovil: It has been discovered recently that the whitish grub of a beetle named Malacosoma lusitanicum makes its home in the bulbs of muscaris and narcissi. These grubs eat out the soft substance of the bulbs, inducing rottenness, and killing or spoiling the bulbs. This pest has become rather common in central France, and in the beetle stage it is seen among various flowers during May, as the larva pupates in April, and the perfect insect emerges in May. The beetles are poor fliers, and therefore are easily caught. Catching the perfect beetle as early as possible and disinfecting the soil in which a crop of infested bulbs has been growing, with bi-sulphide of carbon at 240lb. per acre, or by heavy gas-liming, are remedies suggested, and likely to prove useful.

FRAGRANT ROSES.—H. G., Folkestone: The competition is a novel one, and we should like to have full particulars of it in due course. The difficulty in arriving at a proper judgment lies in the judges themselves, for, however willing they may be to act rightly, they will be unable to give a satisfactory decision, if they have not a keen sense of smell. Further, what is fragrance to one person is a more or less evil odour to another. For instance, some folks love musk odour, others hate it; some are fond of patchouli, others detest it. So that it is just possible the delicate odour of some of the tea-scented roses would not receive their full points when tested by the side of a very richly-scented crimson H.P. However, difficulties are but to be overcome, and the competition promises to be interesting. The following are fragrant roses: Alfred Colomb, red, H.P.; Camille Bernardin, crimson, H.P.; Chas. Lefebvre, crimson, H.P.; Cherry Ripe, light crimson, H.T.; Cheshunt Hybrid, carmine, H.T.; Countess Annesley, rosy salmon, H.T.; Countess of Caledon, carmine, H.T.; Dr. Andry, bright crimson, H.P.; Dupuy Jamain, cerise, H.P.; Exposition de Brie, crimson, H.P.; Exquisite, bright crimson, H.T.; E. Y. Teas, red, H.P.; General Jacqueminot, scarlet-crimson, H.P.; Heinrich Schultheis, pink, H.P.; Hugh Dickson, crimson-scarlet, H.P.; La France, silvery rose, H.T.; Marquise Lita, rose, H.T.; Mdme. Isaac Periere carmine, Bourbon; Maiden's Blush, flesh pink (albà); Marie Baumann, soft red, H.P.; Mrs. John Laing, rose-pink, H.P.; Pio X., creamy-white, H.T.; Red Damask, red, D.; Richmond, crimson, H.T.; Senateur Vaisse, crimson, H.P.; Ulrich Brunner, red, H.P.; Viscountess Folkestone, white, H.T.; and Zéphirine Drouhin, pink, B.

NATURE STUDY.—G. S. G., Wisbech: We sympathise with you; the work is often difficult, especially among the adults. In school gardening there is a sort of gospel that finds expression in Professor L. H. Bailey's "The Nature Study Idea," as follows: "I dropped a seed into the earth. It grew, and the plant was mine. It was a wonderful thing, this plant of mine. I did not know its name, and the plant did not bloom. All I know is that I planted something apparently as lifeless as a grain of sand, and there came forth a green and living thing unlike the seed, unlike the soil in which it grew. No one could tell me why it grew, nor how. It had secrets all its own, secrets that baffle the wisest men; yet this plant was my friend. It faded when I withheld the light, it wilted when I neglected to give it water, it flourished when I supplied its simple needs. One week I went away on a vacation, and when I returned the plant was dead; and I missed it. Although my little plant had died so soon, it had taught me a lesson; and the lesson is that it is worth while to have a plant."

HERBACEOUS PÆONIES. — C. P. F., Saffron Walden: Herbaceous pæonies are less particular as to the character of the soil than is commonly supposed. They will grow more vigorously in a deep rich loam than in a shallow sandy soil, but in the latter they will grow freely and produce an abundance of bloom of good quality, provided it is well prepared and its fertility maintained. The soil should, whatever its character, be liberally enriched with well-decayed animal manure, and be deeply dug. If broken up to a depth of two feet, so much the better; and if the subsoil will not permit of the spade going so deeply, the digging should be as deep as the subsoil will permit. Subsequently the beds and borders should be enriched with manure annually, where the soil is naturally light and poor, and every second year in other cases. The planting may be done at any time from the end of September till about the middle of March. Golden daffodils should be planted rather closely to the crowns of the pæonies, as their flowers are produced when the young growths are rising, and present a rich contrast to them. The following will form an excellent selection of varieties: Admiral Dewey, Agnes Kelway, Alexander Dumas, Cavalleria Rusticana, Duc de Wellington, Duke of Devonshire, Lady Curzon, Lady A. Duff, Leonard Kelway, Miss Mary Best, Mrs. A. F. Hayward, Olivia, Peter-the-Great, Princess Irene, Reine de Francaises, Rose d'Amour, Sir T. Lipton, and Venus.

NAMES OF PLANTS.

J. M.— No. 2, Aloe verrucosa.

J. L. W., Faversham.—The true Freesia refracta alba.

F. J. L., Richmond.—1, Pinus monticola; 2, Galax aphylla; 3, Oncidium varicosum.

R. D., Hertford.—1, Primula frondosa; 2, Iris histrioides; 3, Exacum affine; 4, Spiræa confusa.

A. R., Ilkley.—1, Pteris cretica; 2, P. scaberula; 3, Woodwardia radicans; 4, Todea superba; 5, Alsophila australis; 6, Adiantum cuneatum grandiceps; 7, Davallia hirta cristata.

D. P., Grosmont. — 1, probably Oxalis rosea; send when in flower; 2, Pinus Laricio austriaca; 3, not recognised; 4, Thuia orientalis; 5, probably Picea Albertiana; 6. Cupressus Lawsonianus albo-spica.

Guides to Garden Work.—The publishers of the GARDENERS' MAGAZINE will be pleased to forward a catalogue of their gardening books, setting out full particulars of the contents of each work. The books which are thoroughly practical, up-to-date and well bound, will be of particular service to those interested in flowers, the greenhouse, or the garden. A copy of the catalogue will be sent post free to any reader who addresses a postcard to the Publisher, THE GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, London.

CARNATION HYBRIDISING.

Following the remarks made in our columns recently by Mr. P. S. Hayward and Mr. T. Slade, the following paper, by Mr. Richard Witterstaetter, Cincinnati, O., read before the American Carnation Society at the Washington Convention, January 28 to 30, 1908, will be of interest to our readers.

Some sixteen years ago, when I first undertook the work of hybridising the carnation, I had very little knowledge of Nature's laws regarding the results to be expected from crossing the standard commercial varieties of that date, and concluded that experiments, with a complete record of the parentage and the results, were necessary. As regards colour, size, stem, form, habit, freedom, etc., I found, while we had some very good seedlings that pointed up well in everything except colour—and colour is a very important factor in a commercial carnation—that we had quite a few variegated, purples, and off colours, and very few identical to the parent colour. I concluded, therefore, that this must be Nature's law in plant life, the same as in the human race, and that blood would tell. Hence subsequent breeding was carried on with that point in view, namely, scarlets in a race by themselves, whites in theirs, and so on, always selecting for future work that which came nearest to an ideal as to colour and commercial value.

Difficulty with Scarlets.

Some have held that by following this method you lose constitution. We have proven this to our own satisfaction to be untrue, if a selection of really vigorous parents is made. This opinion may have arisen from the fact that a very brilliant scarlet has no vigour to back it up, our most vigorous scarlets being only a pale or dull red, and if a good constitution and a brilliant colour are combined the result is apt to be a slow and shy bloomer, not up to the commercial requirements. As most of my endeavours have been devoted to the scarlet race—amounting to about one-third of the number of the seedlings raised—I have taken the pessimistic view that it would be an impossibility to produce a brilliant scarlet of free blooming quality, backed up by a vigorous constitution. Of late years, however, I have observed that this will not be an impossibility.

Qualities Sought in Breeding.

In breeding for form we always selected those that had produced themselves in that point for two or three generations, choosing one or the other of the parents, preferably the seed parent, and using the same as a seed parent. In pink we do not hold so closely to the colour line, but are very particular that whatever colour is used shall be of good, clear, strong, and lively tone, not subject to fading into dull colours, nor easily affected by the sun.

In breeding for size we do not hesitate to use a small flowered variety as a seed parent, provided its progenitors of the first and second generations past were large flowered varieties, neither do we fear to use it as a pollen parent, if it has all the other attributes of a good commercial variety.

In breeding for stem and calyx I like to select a variety that has inherited these good points from one or two generations past, with the bloom bordering on the semi-double, or not too many petals to insure a good setting of seeds; also guarding against parents with flowers containing too many petals, as the result will be too many extremely double flowers, with no calyx to speak of.

Vigour of Constitution.

Constitution, next to colour, is the most important factor of a commercial carnation, from a grower's point of view, and should be given the utmost consideration. The parents should be selected and bred to such varieties as are noted for their healthy and vigorous constitution. We believe that in order to gain the best results this crossing should be done during the months of March and April, when plants are making their most vigorous and rapid growth, insuring well-developed and ripened seed.

We sometimes question whether the condition and class of food with which we supply the mother plant when crossing, and up to the time of ripening the seeds, are not responsible, to some extent, for our failures or successes, as the case may be.

Regarding any other points of hybridisation, I might suggest a strong, well-rooted love for the work, untiring patience and perseverance, with a studious observation of the results and with a fair sized bank account at your disposal, until your aim has been attained.

Outdoor Seakale. — This may be blanched like celery by heaping up a pile of earth over the crowns, or packing them round with sweetened, aerated ashes from the stokehole. Earth is, however, preferable, as it gives a nuttier taste to the produce. It should be used in a fairly dry condition, and it is well to look out for slugs during the process. When the heads are fit to cut they will indicate the fact by cracking their covering. This outdoor blanched seakale is often superior in flavour to that produced in the greenhouse.—E. J. K.

GEO. COOLING & SONS'

STRONGLY RECOMMEND THE

New Giant Lily of the Valley.

Fortin's New Large-flowered Lily of the Valley is quite distinct. Being twice the size and substance of the ordinary variety, it produces long, stiff stems and flower-spikes averaging one foot in length, the individual bells being of immense size, and often 18 to 20 on a spike. For pot culture it is unsurpassed, and it will thrive in any ordinary soil out of doors. A most valuable acquisition, which should be found a place in every garden. Strong flowering crowns, per doz., 2s. 6d.; per 100, 15s., post free.

COOLING'S NEW SEED CATALOGUE contains a full list of choice Bulbs and Roots selected for spring planting, forwarded gratis and post free.

NOTES OF THE WEEK.

◆

Solanum etuberosum.

Mr. A. W. Sutton's paper read at the Linnean Society on Thursday, the 20th inst., although dealing with all the recognised species of tuber-bearing Solanums which he had been able to acquire and study had for its backbone, so to speak, the quite recent results of sowing seed of S. etuberosum which, after twenty years absolute sterility, had eventually yielded a single apple or seed-vessel, whence twenty plants had been successfully raised. When it is considered that all potato raisers sow seed from time to time as a means of obtaining new varieties, since the potato plant apparently does not produce bud variations yielding new forms, the mere fact of this sowing of S etuberosum appears to be of trifling importance, but in point of fact by its results it promises to be of very great importance indeed. In the first place it has always been a puzzle to those who take an interest in vegetable pedigrees, to know which of the known wild species of Solanum now existing had given us our culinary potato, which, as everyone knows, has become one of our greatest and most valuable food and industrial factors. The desire to know this became also accentuated when it was considered that as continued artificial cultivation tended to weaken the constitution and render it more and more liable to the well known potato disease, a hark back to the original wild stock might probably give a fresh lease by infusing some of the original vigour and resistant power. S. etuberosum though differing from S. tuberosum, i.e., our common potato, in the haulm and other specific characters, was the only accepted wild species which yielded tubers at all like the commercial ones. When first tested twenty years ago these were no bigger than marbles, and from its botanical name which really means the tuberless solanum, it is assumed that under wild and starved conditions they might be still further reduced so far as to be some justification for the name. Now, however, after twenty years, the tubers have become much larger, and rank, indeed, with fair sized ordinary ones in appearance, and even in flavour. One very essential feature, however, apart from the minor specific differences already alluded to, is that the pollen grains of S. etuberosum agree with those of all truly wild species in being evenly oval, a long egg-shape; while those of the cultivated potato are irregular and vary much in size. The most extraordinary fact has, however, transpired from the one sowing which has been so far possible, that despite these differences, that of the pollen included, which is the most important, the batch of offspring resulting exactly resemble in their general character and their varied nature, a batch raised from the common potato S. tuberosum. No expert, ignorant of their origin, would hesitate in pronouncing them to be S. tuberosum pure and simple. The pollen grains, however, in the one plant examined in this connection, were of the wild oval even form. It must have been a revelation to many of those who were privileged to inspect the parallel crops raised under like conditions from the two plants, viz., S. tuberosum (var. Blue Giant) and S. etuberosum that such a varied brood could issue from one seed pod. Twenty different forms resulted from as many plants raised, varying in size, shape, and colour; white, red, purple, rose, etc., while one was actually purplish-black throughout precisely like a well known S American cultivated variety. Naturally the Mendelians are all agog to know what the next generation will yield, a curiosity which Mr. Sutton may be relied upon to satisfy without delay. Was this batch due to a natural cross by means of pollen from S. tuberosum in other parts of the field, is a legitimate question, this, however, Mr. Sutton considers not to have been likely, self-fertilisation appearing to be the rule. In any case the evidence strongly points to the origin of our precious potato having been found at last, and since, in addition, during twenty years' cultivation, the disease has failed to find a single weak spot in S. etuberosum, the primary object of research, a disease-resisting tuber would also appear to be attained.

MR. EDWIN MOLYNEUX, V.M.H.

Mr. Edwin Molyneux, V.M.H., whose portrait we have the satisfaction of giving in this issue, is so well and widely known in both horticultural and agricultural circles as to render it wholly unnecessary to make otherwise than the briefest reference to the splendid work he has accomplished in the course of an extremely active life. Possessing in an eminent degree the determination characteristic of the higher type of Yorkshireman, and ability of a high order, he was not long in taking a prominent position among practical horticulturists after he had the sole responsibility of a garden placed upon his shoulders. There is no occasion to pass under review his training during the early part of his gardening career, for it is sufficient to know from his subsequent achievements that it must have been thorough, and on lines that conduce to a keen interest being taken in both the scientific and practical aspect of garden management. Many years ago, when the Kingston Chrysanthemum Society was at the zenith of its popularity, a valuable challenge vase, which had to be won three times, was annually offered for competition, and of these vases Mr. Molyneux, who was then head gardener at Swanmore Park, succeeded in winning several. These splendid achievements, and the winning of innumerable prizes in other classes at Kingston and elsewhere, placed him at the head of chrysanthemum growers, and this position he held until he retired from the arena. It may be of interest to mention that Mr. Molyneux's successes as an exhibitor were largely due to his appreciating the necessity of a proper balance between size and finish, and in the latter attribute must be included colour. While growing and exhibiting chrysanthemums with such remarkable success, Mr. Molyneux obtained much distinction as a cultivator of fruits and vegetables, and the gardens under his charge formed an excellent model of what a horticultural establishment of the highest class should be. When, many years ago, a change was made in the management of the Swanmore home farm, this, as well as the gardens, were placed under his charge by his appreciative employer, W. H. Myers, Esq. Mr. Molyneux held the dual position for several years, but as that involved too great a strain upon him he was relieved of the responsibilities of the garden. It would be difficult to say whether Mr. Molyneux has achieved the highest success in the garden or on the farm, nor is it necessary we should make the attempt. We can, however, say that while wholly engaged in agricultural matters, he has in no way changed in the strong affection he has had for the garden from his youth upwards.

Our Spring Number.—As announced in our issue of the 22nd inst., the Spring Number of the GARDENERS' MAGAZINE will be published on March 7, and be of quite exceptional interest. The first of two profusely illustrated articles entitled "Some Famous Cornish Gardens," will be given, and this, we venture to suggest, will constitute a feature of much interest, for the information it will contain relating to the many beautiful plants that have a place in the principal gardens of Cornwall. The other contents will also be such as to strongly appeal to those who are concerned with the garden and its management. Mr. Prinsep will describe the method by which he has achieved so much success in the cultivation of deciduous calanthes. Mr. Stevenson, who achieved so high a degree of success at the exhibition of the National Sweet Pea Society last year, will write on the cultivation of sweet peas for exhibition; Mr. S. W. Fitzherbert will contribute an essay on garden seats; Mr. George Woodgate will state the advantages of spraying fruit trees in winter; Mr. A. Petts will describe the method of procedure by which gardens may be beautified with annuals. Mr. E. Molyneux will write on the advances that have of late years been made in the improvement of lilacs; Mr. T. Coomber will give a short list of the finest long-keeping apples, and Mr. T. H. Slade will give a selection of winter-flowering carnations of special value for private gardens. The care of garden tools, the use of ivy-leaved pelargoniums grown in pyramidal form in the flower garden, moon daisies, standard weeping roses, and some other subjects will also receive attention. In addition to the numerous illustrations in black and white, a plate in colours of garden tulips will be presented with the issue.

Horticultural Club.—The next house dinner of this club will take place on Tuesday next, March 3, at six p.m., at the Hotel Windsor. The lecture will be by Mr. C. E. Pearson on "Bird Eggs and Evolution of Protective Colour," and will be illustrated with lantern slides.

Beech Coccus at Burnham Beeches.—That most destructive of woodland pests, the Beech Coccus (Cryptococcus fagi) has been found in considerable numbers at Burnham Beeches, and the City of London's Coal, Corn, and Finance Committee is taking active steps to stamp it out. The pest has also been discovered among the beeches on a neighbouring estate, the owner of which has consulted the Board of Agriculture on the subject. The committee, alive to the insidious and destructive nature of the attack, has appointed a special sub-committee to deal with the pest by the washing and spraying the affected trees and by other treatment; and it is confidently hoped that the scourge will be stamped out before any permanent or extensive damage is done.

Damage to Trees at Sandringham.—The severe gale that passed over almost the whole of the country on Saturday evening last left its mark in many districts. On the King's estate at Sandringham the fury of the gale wrought great damage to the trees, blowing down large numbers of fine oaks and beeches, some of these crashing through the estate walls in their fall. Sir Dighton Probyn hurried to Sandringham early in the week to inspect the damage and make arrangements for its repair so far as possible.

Pecan Nuts.—The Pecan nut trees are occupying the attention of planters in the South Atlantic and Gulf States of America almost to the exclusion of other nut-bearing trees. The Pecan (Carya olivæformis) is a close relative of our walnut, and several members of the genus Carya are known commercially as Hickories. The Pecan is hardy at Kew, but we do not know whether it has ever ripened fruits there. The nuts are very hard-shelled, but as they are now being cracked and graded by machinery, they are forming a very considerable industry in the Southern United States. There are several varieties cultivated, these having fruits or nuts of varying size and shape; popular sorts are Bradley, Dewey, President, The James, Randall, Daisy, Stuart, and Frotcher. Young trees are rather expensive to produce, but the demand has to be met, and consequently methods have improved. With the exception of C. amora, the Swamp Hickory, all the Caryas are tap-rooted, and almost fibreless, hence the difficulty of successful transplantation. This is overcome by sowing the nuts in trenches in the bottom of which is laid a strip of fine wire-netting or wire cloth; this prevents the formation of strong tap-roots, and it is said that from every indentation made in the root by the wire, strong roots start when the plant is set out in the orchard. Of course, budding or grafting are necessary to obtain the best varieties. From two to five years are necessary for the production of a saleable tree.

United Horticultural Benefit and Provident Society.—The annual meeting of this society will be held at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Monday, March 9, when the chair will be taken at 8 p.m.

Messrs. James Carter and Co., High Holborn, have received the Royal Warrant of Appointment as seedsmen to his Majesty the King of Siam.

Irrigation in Egypt.—At the Royal Society of Arts, under the presidency of Lord Cromer, Sir Hanbury Brown read a most interesting paper on "Irrigation in Egypt under British Direction," on Tuesday, February 25. Sir Hanbury Brown showed how largely the prosperity of Egypt depended upon a thorough system of irrigation, and he pointed out that the cotton crop had doubled in quantity and value till it now realised £15,000,000, the cultivatable area had increased by a million acres, and land had doubled in value since 1883. The Assouan Dam and its connections were increasing the prosperity of Middle Egypt, and the huge reservoir insured the cotton crop of Lower Egypt. Lord Cromer added that £20,000,000 might advantageously be spent on irrigation works in Egypt during the next fifteen or twenty years.

Baltic Rose and Sweet Pea Society. — Under this title a horticultural society, devoted to the culture of the rose and the sweet pea, was organised last year in the City of London, the association being open only to members of the Baltic Mercantile and Shipping Exchange, Lloyd's, and subscribers to the Corn Exchange, with the clerks in their employ. The first exhibition was held in July, and as a result a sum of £20 was afterwards divided between the Corn Exchange Benevolent Society, the Cereals, the Shipbrokers' Benevolent Society, and the Oilseed Benevolent Association. It is proposed to hold a second show in July next. The hon. secretaries are, Mr. B. Hugo and Mr. F. T. Barker, the Baltic, St. Mary Axe.

Basic Slag and Lime.—In an interesting report on manurial experiments on grass land, issued from the University College, Reading, Professor Percival points out that on grass land manured with basic slag, the cattle ate the herbage bare, neglecting plots manured with other substances. Professor Percival suggests the use of basic slag in place of lime or chalk, but while basic slag is most certainly helpful on land in which lime is short or deficient, it by no means follows that the lime it adds is sufficient to render direct liming unnecessary.

Home-Grown Telegraph Poles.—In answer to a question put to him in the House of Commons recently, Mr. Buxton replied that telegraph poles were imported because suitable poles could not be obtained at home. He had invited tenders from all parts of the country, and had, as yet, only been able to place a small order for larch poles with a Welsh firm.

Small Holdings.—We understand that in Buckinghamshire about 330 applications have been made for small holdings, the total area applied for being 6,[illegible] acres. In Wiltshire there are about 3[illegible] applicants for a total of about 6,000 acres, and in Kent there are 281 applicants for 3,805 acres.

Women's Horticultural Exhibition.—The Women's Agricultural and Horticultural International Union is organising an exhibition and sale of farm and garden produce in the gardens of the Royal Botanic Society, Regent's Park, London, N.W. There will be classes for groups of flowers, roses, carnations, sweet peas, choice fruits, hardy fruits, designs for country and suburban gardens, and for decorative effect of flowers. The exhibition will be held on Wednesday, July 15.

Sulphur and Wireworm.—It is now being suggested that seeds fumigated with sulphur fumes may prove the salvation of the resulting crop from wireworm attacks. In the "Agricultural Gazette," a letter from Mr. A. Creasy, Great Bentley, Colchester, shows that the fumigation of seed corn with sulphur has proved a preventive of wireworm attacks over a period of five years in the case of land previously infested with the pest.

Leaf Insects in Captivity.—During the early part of October the Royal Botanic Society accepted as a donation from Mr. W. H. St. Quintin, of Scampston Hall, near York, a number of living specimens of the interesting leaf-insect (Pulcriphyllum curifolium), brought as ova from the Seychelles and hatched in this country. On their arrival they were placed in the Victoria Water Lily House, as being nearest in temperature and other conditions to their native habitat, and there they have remained, a source of interest to Fellows and visitors to the gardens. In their own country these insects feed upon the leaves of the wild guava; here they seem to do equally well upon Quercus ilex, the evergreen oak. Although only partly developed, they are about two inches in length, and should, when fully grown, reach four inches. In form they are somewhat diamond-shaped, the flattened body pale green, with comparatively narrow wings of vivid green. Each wing forms half the leaf, the outer wing carrying the midrib; branching veins run from centre to the edge, in the same way as in feather-veined leaves, and when the insects are at rest upon foliage it is a difficult matter, even when close to them, to distinguish the one from the other. A curious feature is the large flattened appendages found upon each joint of the legs; it looks as if the insect had tried to decorate itself with pieces of leaf torn off. The object is probably to steady it in its flight from tree to tree.

British Association.—The meeting of the British Association will be held at Dublin in September next, under the general presidency of Mr. Francis Darwin, F.R.S. The president of the botanical section, Section K, will be Dr. F. F. Blackman, F.R.S., Professor of Botany, in the Leeds University.

The Irish Potato Crop of 1907 was remarkable for its diminished area and the relatively small yield. The area under potatoes in Ireland was 590,998 acres, as compared with 616,107 acres in 1906. The weight of last year's crop was according to the official returns estimated at 2,246,488 tons, against 2,660,581 tons in the previous year. The falling off in the yield per acre was very great, dropping as it did from 4.3 tons per acre in 1906 to 3.8 tons per acre last season, a yield that is considerably below the average of the ten years immediately preceding, which was 4.1 tons per acre. There was a considerable falling off in the most favoured districts and on the best cultivated land; and on heavy, low-lying land, where planting could not, on account of the saturated condition of the soil, be done until late, the reduction in the yield was very great, and in some instances the crop was practically a failure.

Use of Calcium Cyanamide.—The experiments conducted at Rothamsted, with a view to ascertain the best method of using this new nitrogenous manure, are reported upon by Mr. A. D. Hall in the current issue of the "Journal" of the Board of Agriculture; and the report is of great practical value.

EREMURUS.

The value of eremurus for grouping in the plant border and garden landscape has been abundantly proved within the last dozen years, and it is now possible to see thriving colonies in every county of Britain south of the Dee that are a source of pride to those who own them, thriving with but little cultural assistance, and that mainly in the form of protecting the rising spikes from winds and frosts. They are noble liliaceous plants whose giant spikes, towering high above their own leafage and neighbouring plants, prove more than ordinarily attractive, and many experiments carried out at Kew and elsewhere in the matter of grouping eremurus among low shrubs for the shelter these give to the rising leaf clusters and for the leafy environment, have been very encouraging, and it is possible that, as the cost of flowering roots decreases, we may see plenty of this form of natural grouping in the near future.

EREMURUS ROBUSTUS. [Photo: F. Mason Good.
Flowers soft pink.

In common with many plants from drier climates than our own, there has been difficulty in "timing" their growth with our seasons, but this difficulty has been worn away by rearing the plants from seeds, and the home-reared examples have proved more tractable under cultivation than the imported specimens. Although it is common usage to discuss eremurus as consisting of one type, there are really two, and, as important cultural possibilities are involved, I take this opportunity of again noting the differences and what they teach.

One group, of which E. Bungei, E. Olgæ, and E. Warei, and several intermediate hybrids are examples, are quite different in habit and requirements from E. robustus (see illustration), E. Elwesianus, E. himalaicus, and their forms.

E. Bungei and its Allies.

The kinds of which E. Bungei is the type have long whip-like roots that travel a yard or more from the small crown; tough sedge-like leaves of greyish hue in loose tangles, and flower spikes produced in July. The inflorescences are extremely light and elegant, and often dip to the ground immediately. The plants enjoy a light soil well charged with lime rubble, and will thrive in quite open situations, provided there is shelter from winds, while the need for protection of the rising crown is not marked.

E. Bungei (or aurantiacus) is the oldest species. It has lovely symmetrical spikes of pale yellow flowers seven to eight feet long, one-third of the spike being densely clothed with flowers. A very beautiful plant, the lightest and most elegant of all eremuri. Its forms are: Præcox, an early-flowering mountain form of slender habit; Shelfurd, a hybrid between this and

E. Olgæ, of copper-bronze colouring; Tubergeni, a hybrid with E. himalaicus, with dense and conical spikes of sulphur yellow flowers.

E. Olgæ is a charming species, whose roots are stouter than those of E. Bungei, leaf growth similar, and whose flowers are coloured peach blossom pink. The spikes are clothed with flowers for two-thirds of their length, and are models of perfect symmetry. A good garden plant of ready increase.

E. Warei is a rare plant from Turkestan, with the root-stock and leaves of Bungei. The inflorescence is a very slender spike of orange-salmon flowers with purplish exterior, giving a curious and attractive colour note. Its varieties are Mrs. Reuthe, with pale yellow spikes that are close to E. Bungei præcox, and even more elegant. A striking feature is the prominent orange-red anthers that recall the finest species of hypericum. There are, in addition, two French hybrids I have not seen.

E. robustus and its Allies.

The plants of this group have huge root-stocks, not unlike a cart wheel, minus its tyre. The leaves are in broad funnel-shaped clusters, and are green throughout, somewhat brittle, and are like those of the maritime squill in many respects. The spikes are stout and upstanding, often 10ft. high, and are covered for quite half their length with many hundreds of showy flowers. These plants enjoy a deep, well-worked loam, full of humus, and it is only in such soils that one can secure the finest growth. The rising crown is peculiarly susceptible to damage by frosts, and all the species in this group need the protection of bracken strewn about and over them till the spike is well advanced. This group needs the most sheltered positions, and in one garden at least I know of, the greatest difficulty is experienced in bringing eremurus spikes to maturity, owing to the bad position of the site.

E. himalaicus is an old garden favourite with the habit of E. robustus, but somewhat denser in the spike, and as the flowers finish the top of the spike keels over. Quite a familiar white eremurus, and often 10ft. high. E. him-rob is a hybrid between this and robustus, with the palest pink flowers, really a blush-pink, and identical with E. himalaicus var. robustus.

E. robustus is a magnificent species with stout stems of soft pink flowers, often exceeding 10ft. in height. It is among the first species to grow, and is peculiarly susceptible to injury from frosts. The spikes quickly follow the leafage, and when they are a foot or more high should have bracken strewn about them, and lightly placed over them at night. The varieties are Elwesianus, a superior plant to the type, with rose-pink flowers of particularly massive outline which develop a week after robustus; the leafage of this form is much more rigid and the crown is not so conical; albus, nearly pure white and distinct from himalaicus in many respects; Elwesianus albus, a rarity I have only seen once, differs from the latter variety in all those points which separate Elwesianus from the type.

The rearing of eremurus from seeds although literally a seven years' business is really a matter the average gardener can take up. Every species and many of the hybrids produce seeds freely, and these germinate in the following spring if sown in the autumn of the year in which they ripened. Choose a light soil in a slightly shaded situation, and cover the seeds with an inch or two of soil. The first year's growth is a pallid inch or two of leaf, the next year's growth is but little better, but in the third and fourth year when the familiar thonged root-stock is formed growth is very rapid. The only way of aiding the seedlings is to water them and shade them if needed—keeping them active as long as possible. Their first season's growth is little more than a month's duration normally, but shading and watering makes it three, and every month's growth so gained "tells" considerably in the long run, and shortens the seedling stage by a year or perhaps two. Lift biennially, and replant all seedlings, but established clumps are really better if quite undisturbed. It is from old-established roots that the finest and strongest spikes are developed, and as an instance of this I may cite one 15ft. spike in perfect development, and four others less tall from one crown planted five years ago.

G. B. Mallett.

DIELYTRA SPECTABILIS AS A POT PLANT.
Flowers deep reddish-rose.

DIELYTRA SPECTABILIS.

For the better part of a hundred years this fine herbaceous plant has been a popular garden subject, and though during the period that has elapsed since its introduction great improvements have been made in matters horticultural, and many have been the new and beautiful plants introduced, it does not lose anything of its popularity, but still remains one of our best border plants, and one of the most useful, elegant, effective, and easily grown of early-flowering plants. Quantities of the irregular fleshy roots are annually imported for forcing, but there seems to be no good reason why it should not be grown for this purpose at home as well as abroad. Not only is Dielytra spectabilis a most useful plant for professional gardeners who have conservatories to keep gay, rooms to furnish, and groups to arrange, but it is one of the very best of plants for an amateur to grow, because, if very early flowers are not wanted it may be grown in pots in a cool house.

In heavy soils and low-lying districts Dielytra spectabilis sometimes suffers from late spring frosts, but usually it is a success, and needs no special treatment, although a thinning out of growths when a clump is long established, the support of a few thin sticks, and an occasional thorough soaking with liquid manure are matters worthy of attention, inasmuch as they bring their reward.

The graceful racemes of rich rose-coloured, inflated flowers are too well known to need description, but well flowered growths with their own elegant leafage, are charming in a cut state for vases. Of course we all know that this old favourite should be called Dicentra but we have known it so long as Dielytra—though that title itself ought to be Diclyrta—that we adhere to the name we are familiar with.

B. C.

Pruning Outdoor Roses.—The end of March is generally a safe time to commence rose pruning in the South of England and the work can thence be gradually pushed on to a conclusion. There is no need to be alarmed or to be rushed into premature pruning because a little growth is pushed from the top buds of a few shoots. These serve a useful purpose in exciting early root action, and when they are removed in the course of pruning proper, dormant buds soon burst into vigorous growth as a result of this root activity. If plenty of flowers for cutting or garden decoration are wanted, do not be too severe with the knife; eight to ten buds per strong shoot are none too many to leave. E. J. K.

By Appointment. By Appointment.

WEBBS' SEEDS

WEBBS' NOVELTIES IN GARDEN PEAS

WEBBS' NEW PIONEER.

First Early. **3/-** per quart.

"I have no hesitation in saying that Webbs' Pioneer is the best Early Pea one can grow."—Mr. G. MERRY, The Ashe Gardens.

WEBBS' STOURBRIDGE MARROW.

Second Early. **2/6** per quart.

"Your Stourbridge Marrow Pea is excellent, both for quality and yield." - Mr. E. AVERY, The Gardens, Finstall Park.

WEBBS' NEW KAISER.

Main Crop. **3/6** per quart.

Awarded R.H.S. Certificate of Merit.

"Webbs' New Kaiser Pea is splendid, a heavy cropper of excellent flavour." —Mr. J. MURBY, The Gardens, Forest Grove.

WEBBS' MASTERPIECE.

Late Crop. **3/-** per quart.

"Webbs' Masterpiece is among the very best late varieties."—Mr. E. BECKETT, The Gardens, Aldenham House.

PLANTS PROTECT MONEY

WEST'S PATENT GARDEN SUNDRIES

SAVE, & LABOUR EASE.

Have been invented during 25 years of practical experience in horticultural sundries, that by the better cultivation of plants and the pleasure by which gardens are kept in order their expense is doubly repaid.

ORDER FORM. *(Address here.)*

(To be filled up and handed to your Seedsman to execute for free delivery, thus saving carriage.)

To Messrs. Kindly supply the following:

WEST'S PATENT GARDEN SUNDRIES.

Qunty.		£	s.	d.
,,	**Rafflatape,** coils better than raffia. 1d. coil ties up 150 plants. 7 coils (100 yds.) for **6d.**			
,,	,, reels, with holder to fasten in buttonhole, 250 yds., complete **1/6** each			
,,	**Wall Tree Fasteners,** aluminium. Fastens on and off any nail in a wall, 50 for **1/-**			
,,	**Powder and Spray Syringe,** most useful article, **6/-** each			
,,	**Nicofume.** Complete self-contained fumigator, holding ½oz. 95°/₀ nicotine, **6d.** ea., **5/9** doz.			
,,	**W.E.O.N. Insecticide.** Sold under a £20 guarantee. 6d. bottles **5/9** doz., **14/-** pint.			
,,	**Fumigator.** Copper cup, complete, **9d.**			
,,	**Hand Fumigator, 2/9** each.			
,,	**Powder Diffuser, 6d.** each			
,,	**Tobacco Powder.** Specially prepared (introduced 1888), **6d.** per tin			
,,	**Westite.** The first and best slug and germ killer, **6d.** per box to **20/-** cwt.			
,,	**Beetle Killer Powder, 6d.** per tin			
,,	**Plant Pot Crocks.** For perfect potting, prevention of insects into pot, etc., **2/9** per 100			
,,	**Fertiliser.** Perfect plant food. Has stood the test for 20 years, **6d.** per box to **20/-** cwt			
,,	**Watering Can Spreaders.** Fits any watering can and gives a splendid spray, **3d.** each			
,,	**Weeder.** Saves weary weeding, for a lady can uproot hundreds of weeds per hour, **2/6** ea.			
,,	**Lawn Sand.** Has stood the test for 25 years, and now improved, **6d.** per tin to **20/-** cwt.			
,,	**Weed Killer.** Best and cheapest for killing weeds on walks, etc. Introduced 1888. **1/6** tin			
,,	**Aluminium Labels.** When written on with lead pencil the wording is legible and indelible. Founded on the 25 years' experience with the West's Patent Label. **1/6, 2/- & 3/-** per 100			
,,	**Layering Pegs** and **Verbena Pins, 9d.** per 100			
,,	**Greenhouse Shading.** Introduced in 1888 and still the best. Green and cream, **9d.** box			
,,	**Garden Cuffs.** Keeps the coat cuffs clean. No gardener should be without them, **6d.** pair			
,,	**Flower Holders.** For button holes and ladies' sprays. The flowers are gripped and held in watertight nickel tube, so that the lady's may be worn downwards { Gent's, **7½d.** Lady's **10d.**

To Readers of THE GARDENERS' MAGAZINE.

SPECIAL OFFER OF 1200 GIANT FLOWERING SWEET PEA SEEDS 12 Distinct Varieties

In order to popularise our famous "Gem" selection of Sweet Peas, we make this very special offer of 1,200 seeds in 12 different giant flowering varieties for **2/9** to readers of this paper. These seeds are carefully selected by us from the most perfect stocks grown, and include the following varieties, which all lovers of these beautiful flowers will recognise as unrivalled in range of colour, size of flower, and general good qualities.

"Dorothy Eckford," "Countess Spencer" (re-selected), **"John Ingman," "Helen Lewis," "King Edward VII," "Scarlet Gem," "Hon. Mrs. Kenyon," "Black Knight," "Miss H. C. Philbrick," "Romolo Piazzani," "Navy Blue," "Agnes Johnson."**

Our **1908 Illustrated Seed Catalogue** is the only Catalogue issued which contains trial ground reports of Garden Seeds. It will be sent free on request or together with a trial packet of seeds for **3d.** to cover postage.

ASYSTASIA BELLA.

The genus Asystasia contains a goodly number of known species, but few are in cultivation, and of these none is better than the subject of this note, of which I send a photograph. As a pot plant Asystasia bella, or, as it is perhaps more generally known under cultivation, Mackaya bella, is sometimes rather disappointing, but planted out it forms a fine specimen shrub of some six or more feet in height, bearing an abundance of its attractive inflorescences. The plant portrayed in the photograph is one grown here in the succulent house among such plants as agaves, dasylirions, and other plants of a xerophytic character. It receives a maximum of sunlight, which ripens the strong growths, and during winter water is withheld to suit the plants with which it is associated.

A FINE LAWN GROUP OF THE JAPANESE SNOW-BALL TREE (VIBURNUM PLICATUM) AT KEW.
Flowers snowy-white.

Perhaps the most important point found necessary, and adopted here, to insure free flowering is that of pinching or breaking out all the young growing shoots, of which an abundance are formed after the appearance of the inflorescences. This gives strength to the flowers and allows their proper development, but if these axillary shoots are allowed to remain the plant has a tendency to produce growth at the expense of bloom. After flowering the old shoots are removed to allow air to reach the young growing shoots. Under this method of treatment the plant, in the Edinburgh Botanic Gardens, flowers well every year, and during spring is for some time an interesting subject to visitors.

Mackaya bella is a native of Natal, and has been figured in the "Botanical Magazine," t. 5,797. It belongs to the order Acanthaceae, and has flowers from one and a half to two inches long, and campanulate; the throat is delicately pencilled with many lines of purple, the body of the corolla being of a pale lilac colour. Plants may be easily grown from cuttings, and a good compost of loam suits them admirably. R. L. Harrow.

Royal Botanic Gardens, Edinburgh.

THE JAPANESE GUELDER ROSE.

Viburnum tomentosum var. plicatum, when well grown and flowered, is one of the handsomest of hardy deciduous shrubs, whilst it is one that continues to improve as it advances in age, over many years, and is thus unlike some subjects, which require renewing every eight or ten years. In some respects it resembles our common guelder rose, or snowball tree, V. opulus var. sterile; it is, however, of dwarfer, more compact habit, bears larger and denser heads of flowers, and longer, plicate leaves.

The species, V. tomentosum, is in itself an ornamental plant, in fact more so than V. opulus, the flower heads being larger and the sterile flowers more conspicuous. It was introduced from Japan many years ago, but is not so well known as the sterile variety plicatum. A very fine variety, in which the heads of flowers are fertile and sterile intermixed, has been put into commerce within the last few years; this is known under the name of Mariesi, and forms an extremely ornamental shrub. A form of the variety plicatum, known as plicatum grandiflorum, is in cultivation; it is recognised by its enormous flowers and flower heads; it would, however, be impossible for it to be more floriferous than the type. The freedom with which the flowers are produced is admirably shown in the accompanying illustration of a lawn group.

Under suitable conditions V. tomentosum and its varieties grow to a height of at least eight feet, with wide-spreading heads. They thrive best in rich loamy soil, and are improved considerably by a top-dressing annually of well-rotted manure. Propagation is effected by means of cuttings during summer. These are made from four to six inches in length and inserted in pots of sandy loam in a warm propagating case. As soon as rooted they are hardened off, and kept in a cold frame until spring, at which period they are transferred to a nursery border. The inexperienced propagator may have greater success if he layers a few of the lower branches out of doors in March, leaving them without disturbance for twelve months.

For forcing early in spring V. plicatum is a very desirable plant, as it never fails to give a good account of itself. It is also one of the shrubs that may be let go for years with no other pruning than the removal of a little wornout wood now and then. W. Dallimore.

Kew.

Parsley in Boxes.—During the late severe weather a few roots of parsley in pots and boxes have been a veritable boon, especially when the snow laid deep on the ground. If the cold has not injured the outdoor parsley crop, it has doubtless checked growth, and where there looks like being a shortage it will pay well to dig up and box a few roots. A deep box should be used, so as to avoid too much shortening of the tap roots. All dead and unusable foliage should be cut away, and the side roots trimmed in to half their length. The rots should then be placed a few inches apart in the box, and filled round with some old potting soil. If watered in and stood in a corner of the greenhouse, where it is warm and moist, a plentiful supply of nice new leaves will soon be forthcoming.—E. J. K.

THE MOUNTAIN KNAPWEED.

Although one of the oldest of the occupants of the herbaceous border, the Mountain Knapweed or large cornflower (Centaurea montana) is by no means the least attractive or interesting. Growing to a height of about 2ft., the species and its varieties possess so vigorous a habit that a strong plant will form a specimen three or four feet in diameter in the course of two or three years. The comparatively short period in which a large and most effective specimen can be obtained is a great advantage where the border is spacious and bold groups desirable; it is somewhat of a drawback in the case of borders that are of limited area. It may be desirable to devote the space which borders of the latter class afford to subjects of more moderate growth; and when the Mountain Knapweed is given a place in them care must be taken to so restrict the growth as to prevent injury being done to less vigorous neighbours. To state the case generally, Centaurea montana and its varieties present an attractive appearance both in large and small borders, but they are more suitable for the former than the latter.

WHITE MOUNTAIN KNAPWEED (CENTAUREA MONTANA ALBA.)

The flowers are produced on stout stems of the height mentioned above, and the flower heads of healthy plants have a diameter of about three inches when the ray florets are expanded, as shown in the accompanying illustration of the white form. The colour of the flowers of the type are rich blue, and those of the varieties rosea and alba are rose-pink and white respectively. The best effect is perhaps produced by so arranging the several forms as to have specimens or groups of distinct colours; but as the colours harmonise there is no objection to their being intermixed. As they thrive in any ordinary garden soil there is no occasion to specially prepare the borders for them, and owing to their vigorous growth they require much less manurial matter than do the majority of hardy perennials. It is a good rule not to apply manure in the form of top-dressings or otherwise until it is seen that it is really necessary. Planting may be successfully done at almost any time between October and March, and the present is as good a time as any for lifting, dividing, and replanting, but there should not be any great delay.

O. P. Q.

Border Carnations that have been wintered in cold frames may now be planted out on well-prepared, but not freshly manured ground. On cold, heavy soils wood ashes, mortar rubbish, and leaf-soil may with advantage be given. Plant with a trowel, make the soil firm all round, and protect from damage by birds. Carnations planted in autumn should now be again examined, making the soil firm, and filling up the blanks.—E. F. Hazelton, Knowsley Gardens.

CARROTS ALL THE YEAR ROUND.

To secure an unbroken supply of fairly young carrots throughout the year at least four sowings are necessary. The first must be made in January on a specially prepared hotbed, under a pit or frame; another early in March outside. The usual maincrop one, and another to carry the supply through the winter. The forced crop will by this date be well advanced and soon provide small, but appreciated roots for the table.

What I wish to more specially allude to now are the three outside crops, it being the season when attention has to be given in the preparation of the soil and sowing of the two first. For the earliest sowing a deeply-dug, well-manured, and sheltered south border should be selected, to encourage the plants to grow and mature as rapidly as possible. The early French Shorthorn varieties are much to be preferred for this purpose, as, in a suitable position and a genial spring, they will produce useable roots in a surprisingly short time—in March. After feeling convinced that the soil is in suitable condition, draw out drills from north to south at twelve inches apart and about one inch deep; sow the seed evenly and more thickly than is usual for the main crop. Should the soil be hard or lumpy cover the seed over with sifted soil from the potting shed or refuse heap. When the young plants can be seen in the rows ply the Dutch hoe between them to aerate the soil as much as possible, and in every way encourage growth. At the highest portion of the border the first and largest roots will be found, and if these are carefully sorted out without injury to the lesser ones the plot will produce carrots over a long period.

The beginning of April will be a good time for the maincrop sowing. As this is an important crop there are several points that should be born in mind. Wireworm is often a dreaded enemy, and to keep it at bay the soil of the beds should be carefully considered. An ideal soil is one that is rather deep, open, and inclining to a sandy nature. A dry day is essential for preparing the soil for the seed, it can then be readily worked down finely with the fork and rake. This point cannot be too strongly impressed on beginners, as germination is never satisfactory and growth always sickly when seeds are sown while the ground is wet and sticky. At the time of preparing the seed bed a light dressing of soot should be stirred in. Some people sow in rows at twelve inches apart, but I prefer three inches wider to allow full leaf development.

The choice of variety is great. For all round purposes the Intermediate varieties that our leading firms offer are the best for the main sowing, and are to be preferred to the longer kinds, which often become broken. After the young plants have appeared above ground, and are about an inch high, a light dressing of nitrate of soda on a damp or dewy morning, about once a fortnight, will promote a desirable and healthy growth, and materially assist in warding off insect attacks. Green-fly is liable to show itself on the foliage, but this is not serious, as it can be easily dealt with by damping the leaves over with an insecticide. As with earlier crops, keep the surface of the soil frequently stirred by hoeing, and thin the plants gradually to at least eight inches apart. Remove all weeds as they show themselves.

If the land has been deeply dug it is not often that much watering is required crop, but if the plants are seen during exceptional drought a thorough soaking will be necessary. Should be required for exhibition frelight dressings of artificial manures, watered in, will help to swell up the large dimensions.

The late crop will require a border, and has carried an early crop of potaafford an excellent site, and the in good condition to receive the The French Shorthorn variety is this sowing. The plants will not much thinning, and the roots may and drawn as in the case of crop. By leaving the roots in through the winter, and giving protection during frosty weather, a of tender young carrots will be proil the early forced ones are ready.

mondely Castle Gardens.

THE WILD GARDEN—II.

Many bulbs are well adapted for naturalising in the open ground. Of these the most effective and the most largely used is the narcissus; in fact, in many cases, the attempt at wild gardening begins and ends with the planting of these bulbs.

Narcissi should never be set out in lines, circles, squares, or in little clumps at equal distances apart. Such grouping invariably destroys the natural effect which it should be the aim to produce. The flowers should appear as informal drifts of colour on the grass, massed towards the centre of the group, and growing more scattered at the edges, with here and there an outlying colony distant a pace or two from the main body. Groups should always be composed of a single variety, and should be set at such distances apart that each forms a picture by itself. Mixed collections should never be planted, since they exhibit such diversity in colour and height as to effectually dispel the sense of repose that should ever invest the wild garden. Groups of early and late-flowering varieties may be planted close to one another without producing an unpleasing impression, as the blossoms of the former will have withered before the latter have commenced to expand. Beautiful pictures may be provided by planting narcissi of distinct varieties by the thousand in meadows, parks, orchards, and open woodland glades.

The great merit of spring-flowering bulbs is that they bloom before the grass commences to grow and the foliage is withered before the season of haymaking arrives, so that they may be planted in fields laid down to grass without interfering with the annual mowing. The wood anemone spangles many of our copses with its silver-white blossoms in the springtide of the year, and there are others of the family that may be naturalised with the most charming results. The blue Anemone apennina soon makes itself at home, and spreads rapidly in almost any situation, creating a delightful picture, with its cloud of azure thrown into relief by its green setting. The Greek A. blanda is another beautiful flower, ranging in colour from blue to purple and almost white. It is not such a vigorous grower as A. apennina, and so should not be planted among coarse herbage, as that species may be with every prospect of success, but relegated to some gently-sloping bank covered with fine grass, where it will for years afford a pleasing sight when in flower. The scarlet A. fulgens has been tried with fair success in the grass in some places, but is not to be relied on as are the other species mentioned.

The Dutch crocuses, in their hues of yellow, purple, and white, are excellent for planting beneath deciduous trees, where in the early spring they furnish a glorious display with spreading sheets of rich colour, while the autumn-flowering C. speciosus is charming on grassy banks. The chionodoxas and scillas are lovely little blue spring-flowering plants that adapt themselves readily to naturalisation. Of the former, C. sardensis, deep blue with a white eye, is the most effective for massing, and C. Luciliæ, with larger blue and white flowers, is also good.

Our native wild hyacinth, or "bluebell," which, in the late spring, veils the woodland glades with the azure of the sky, is known to all, and other species of the family, such as S. hispanica and S. italica, with the dwarfer-growing S. bifolia and S. sibirica, as well as their white varieties, will be found useful on banks. The muscaris, or grape hyacinths, are another attractive race, of which M. conicum Heavenly Blue, very rich in colour, is one of the best, and is very beautiful when spreading a sheet of deepest blue over a gentle slope.

Several of the cyclamen family are par-

A SUCCESSFUL EXAMPLE OF NATURALISED DAFFODILS IN A WEST COUNTRY GARDEN.

Hamamelis mollis.—The various of Hamamelis are deservedly popular their flowers are exceedingly and borne either in autumn, H. virginica, or from Christmas until of January. Several of them are by reason of the twisted, spiderywhich stamp them as distinct The species under notice introduction than the fails to surpass the rest in beauty. It is of Chinese is stated to attain a height of native habitat. Under cultivait appears more inclined a large bush, rather than great height. The leaves are and pubescent, and quite distinct any other species, while the from those of other sorts by golden petals straight, except hooked, whilst in the other species they are twisted. It rich loamy soil, and starts best when an addition of leafis made to the compost.—W.

ticularly good for naturalising. C. coum, with its varieties Atkinsi and ibericum, which are often in bloom with the snowdrops, are best planted on sheltered banks, where they will spread rapidly and display their lovely blossoms, ranging in tint from crimson to white. C. neapolitanum, often known as C. hederæfolium, which flowers in September, and whose beautifully marbled leaves are borne through the entire winter, is most valuable for carpeting the surface beneath trees, even growing well under the dense shade of evergreens. In Cornwall it may be seen in the best of health beneath large specimens of Pinus insignis, covering the ground from the trunk to the outer branches with its handsome foliage.

The Winter Aconite, Eranthis hyemalis, must on no account be overlooked, since it makes a charming picture when naturalised by the thousand beneath deciduous trees, where its cloud of bright gold shines afar. Of the fritillarias the Crown Imperial, F. imperialis, with drooping yellow and orange-red bells, looks well in the open spaces of woods, and the Snake's-head Fritilliary, F. meleagris, with its white variety, is lovely in damp meadows.

Many species of lilies may be planted with every prospect of success in open spaces in the woodland, where they will create a charming feature when in flower, and will benefit by the shelter and partial shade afforded by the trees. No more noble picture can be imagined than a large group of the stately lily of the Himalayas, L. giganteum, with a dozen or more towering stems, ten feet and over in height, set with the long white trumpets, which exhale a vanilla-like fragrance. On the banks of streams, or in ground through which moisture from a higher level percolates, the swamp lilies, L. superbum, L. canadense, and L. pardalinum, should flourish if planted in sandy leaf-mould, while L. candidum, L. Henryi, L. martagon, L. chalcedonicum, L. croceum, L. pyrenaicum, L. Szovitzianum, and L. umbellatum should thrive in the opener parts.

In conclusion, mention must be made of the snowdrop. There are few more beautiful sights than that afforded by countless thousands of the Fair Maid of February blossoming chastely in grassy glades and in the open woodland. Where they succeed they will increase rapidly by self-sown seed, and create a delightful picture while winter is still with us.

S. W. Fitzherbert.

Coronilla glauca. — Introduced from Southern Europe in 1722, this coronilla was much better known to the old-time gardeners than to those of the present day. It was at one time grown as a market plant, but was superseded by Cytisus racemosus, which is now cultivated in such large numbers. In the coronilla the leaves consist of from five to seven leaflets, quite smooth, and of a pleasing glaucous green tint, somewhat the same shade of colour as occurs in the leaves of the common rue. The flowers are borne in rounded clusters often throughout the winter and spring months, and are of a clear yellow colour. Compared with the cytisus, this coronilla is more particular in its cultural requirements, as it quickly resents an excess of water at the roots, and at the same time they must not be allowed to become dry. Ordinary greenhouse treatment suits it well, and it may be stood out of doors during the summer months. For the embellishment of the conservatory large bushy plants may be grown in pots or tubs, and in this way they yield a wealth of blossom. There is a form with variegated leaves which has been grown for at least forty years. Coronilla glauca forms the subject of tab. 13 of the "Botanical Magazine."—W. T.

MONTBRETIAS.

It would be very difficult to find more charming or more useful border flowers for contributing to the charms of the flower garden during the months of August, September, and October than the montbretias. For massing in beds, where a bright group is required in the months stated, the plants can be used with telling effect in the flower garden. An abundance of flowers, which last a long time in perfection, rapid growth, and a quick increase, as well as adaptability to house decoration in a cut state, render them so useful as to justify their steadily increasing popularity.

Originally montbretias came from the Cape of Good Hope, and although there are a few older kinds, Montbretia Pottsi, introduced in 1877, marked the commencement of growing these flowers in the open border. Although rich in colour, this species is too niggardly in the quantity of its flowers to be of much value in an up-to-date collection, and has not, in consequence, been largely planted of late. During the last ten years great advances have been made in the raising of new and improved forms of montbretias, with the result that numerous desirable varieties are available. Mr. G. Davison, gardener to Major Petre, Westwick Hall, in Norfolk, has devoted much attention to montbretias, and as the result of his well-directed efforts has raised a large number of extremely beautiful varieties.

Cultivation and Propagation.

The culture of montbretias is comparatively easy, for all that is required is an open space, and deeply dug, well enriched soil. That of a sandy character is preferable, and where the soil is heavy, cold, and retentive of moisture it should, if practicable, be replaced with a mixture of a porous nature, such, for example, as leaf mould, sand, turfy loam, and wood ashes, adding a little peat if possible. When once montbretias are allowed to grow into a mass, where light and air cannot reach the stems, the results are very poor in every way, as compared with those obtained by a proper system of cultivation. Ample space is important, and in making a new clump, which should be done every second year when they are growing in the border, the plants should have six inches of clear space. Plenty of moisture during the growing season is an advantage, and much benefit is derived from liberal mulchings of horse manure and half-decayed leaves. The bulbs may be planted at any time from November to March.

Propagation is effected in two ways, namely, by seed and division. The former is interesting, especially when an endeavour is made to raise new and improved varieties by cross-fertilisation. The seed should be sown as soon as ripe in sandy soil, in gentle heat. When the seedlings are large enough to handle they are pricked out in boxes and kept growing all the winter, consequently they are strong enough in May to be put out in a properly prepared position. Some of the strongest plants will flower in August, and the remainder in the year following. Although these montbretias are hardy with some surface protection, it is wise to take up the seedlings and winter them in boxes or frames in sandy soil. Early in February divide them singly, planting again in frames or boxes. By the middle of April they will be strong, with abundance of roots, and with care can be lifted and transplanted to where they are to bloom without any check.

When increasing the stock by division sort the bulbs into two sizes, and as they commence to grow in the spring the stolons, if taken off and planted for a time in boxes, grow away vigorously, and make even better plants than those produced from the bulbs.

Choice Varieties.

The following is a selection of the newer and more desirable varieties, and these, with the exception of some few sorts which I will name, are all that are necessary to grow. M. crocosmæflora, rich orange-yellow tinted with red, is a very popular, cheap, and effective variety, much used for cutting. Germania is vigorous in growth, often attaining a height of three feet, and producing graceful, free-branching flower spikes bearing large, widely expanded flowers two or three inches across. The colour is a rich glowing orange-scarlet with a red throat. M. Messidor is a distinct new seedling of French origin; the growth is tall, with much-branching spikes, colour, maple yellow passing to pale yellow; a capital variety in every way. The following are hybrids raised by Mr. Davison:

George Davison was raised from Golden Sheaf, an imported variety, and it is the seed parent of all the hybrids. The blossoms are pale orange-yellow, tinted deeper externally, and three inches across. In growth it is vigorous, being from three feet to four feet high, and much branched.

Hereward has recurved flowers, as in a martagon lily, quite three inches in diameter, very freely borne on tall erect stems. In colour they are pale orange; quite late in flowering, thus they are most valuable.

King Edmund grows from three feet to four feet high, is much branched, bearing close spikes of rich golden-yellow flowers, deeper tinted externally, and marked with six to eight chocolate spots at the throat. The flowers are quite three inches in diameter, the broad petals expanding to the fullest extent, the tips being held quite erect, thus showing the centre of each flower.

Lord Nelson is the richest in colour of all montbretias; the flowers are orange-scarlet and crimson externally, with a yellow centre. The stems are dark purple, which adds to its beauty.

Lady Hamilton has well-formed flowers, which are yellow, with a suffusion of rosy-orange in the centre when opening, changing with age to apricot. This is an erect-growing variety three and a-half feet high.

Prometheus is much the finest of all montbretias, quite a giant in growth and size of flower, reaching four feet high. The blooms are three and a-half inches in diameter. In colour they are rich orange, flushed and stained with crimson.

St. Botolph has the largest flowers of any yellow montbretia, and these are suffused with a ruddy orange exterior. The blossoms are three inches in diameter, freely produced on branching stems four feet high.

Westwick grows three feet high; in colour it is quite distinct, rich orange-scarlet flushed with deep red externally; around the clear buff-yellow centre there is a rich crimson zone, with a few markings of flame-like colouring at the throat.

In addition to the above Mr. Davison has another new variety, named Nov which is of remarkable quality. It grows to a height of three feet six inches, and is much branched. The number of branches it produces is remarkable, and what a mass of flowers is obtained from even one strong plant, which will, when established, push up three or four stems. The large flowers are rich yellow, with a deep orange-red exterior.

E. Molyneux.

LATE DESSERT PEARS.

There is considerable variety even among late dessert pears, although the quality of many is only second-rate, at least in some localities, though this is probably due somewhat to soil influence, as it seems difficult to otherwise account for the variation shown by many late varieties grown in different parts of the country.

A variety often seen in Devonshire is Huyshe's Victoria, one of a trio raised by the Rev. John Huyshe, of Clysthydon. This one is the best of the three, and is a useful free-bearing variety of excellent flavour, especially when grown on a wall. Its season, according to position, is December and January. Beurre Sterckmans is a large late pear of very good quality, and fine fruits of the variety can be obtained from cordon trees.

Le Lectier is a variety of more recent introduction, and is an exceptionally vigorous grower on the quince. It is a fairly large pear, but can scarcely be described as handsome, as it is generally a straw-yellow in colour, without any russet or warm tints. With us it can only be classed as second-rate in quality. Another large late-keeping pear is Marie Benoist, apparently a prolific bearer, but though it has the merit of size, it is only second-rate in quality, and therefore disappointing. Among late pears it appears to be only the small and medium-sized varieties that can [illegible] be described as delicious.

Knight's Monarch is generally a heavy cropper, the fruit growing in clusters that [illegible] thin themselves. Well-grown fruits can sometimes be obtained, good in quality and appearance, but the variety is not one of which many trees are required. We have had it good, but more often good-for-nothing. Nouvelle Fulvie is an excellent pear in quality, and of handsome appearance when the fruits are exposed to the sun, a first-rate pear, and good as a cordon. President Barabé is a delicious variety, melting and juicy. It is a prolific bearer, and should be in every collection. The fruits are of medium size. Olivier de Serres is one of the best-flavoured pears grown; it is not by any means a strong grower on the quince. The fruits should be thinned freely to increase their size, otherwise they come rather small.

Two late pears, which vary considerably in different soils, are Winter Nelis and Glou Morceau. The first-named does not make sufficient growth with us to produce much of a crop, and is far from satisfactory, indeed scarcely worth growing, and Glou Morceau is much the same in this respect here, yet some two miles from us I have seen fine fruits of both these pears, grown in a light and warm soil, which evidently is what these varieties require.

Duchesse de Bordeaux is very good in quality, and evidently a pear that requires good cultivation to bring it to perfection. The medium-size fruits should be well thinned. Easter Beurre is not so good as usual this season. It grows to a fair size if thinning is carried out. A delicious pear, where it is satisfactory, is the Forelle, or Trout pear. Its handsome appearance when grown in a warm position would commend it, and this, with the good quality of the fruits, should give it a place in every collection. Chaumontel is only worth growing for the sake of variety, for it is surpassed in flavour and cropping by other kinds.

Josephine de Malines is much better grown against a wall than in the open borders. The fruits are of suitable size for dessert, and if exposed to the sun they assume a handsome appearance. Passe Crassane is another very good late pear which should be planted where variety is required, and variety is more necessary for private supplies than would be the case for market. In gardens it is not the quantity of one variety that is needed so much as a constant supply as long and late in the season as possible.

There are other varieties not enumerated here which may be grown, but those given comprise the best in their season. The past year was not a good one for late pears, as the fruits have lacked colour, and the flavour has not been altogether first-rate. Many have not kept well, as there was too much moisture in the fruits and lack of saccharine matter, want of sunshine being doubtless responsible for this deficiency.

Poltimore Gardens.

CYPRIPEDIUM FAIRRIEANUM

There is no need to again relate how for long years the orchid collections of the country were without the quaint, yet pretty, Cypripedium Fairrieanum, or how collectors hunted for the species, or even how at last the long-lost plant was discovered in quantity. It will suffice now to say that the species is plentiful in cultivation, and no collection need be without it. A firm that has been particularly successful with these, as with all other cypripediums, indeed with all kinds of plants it cultivates—is the Cheltenham firm of Messrs. Cypher and Sons. Last October the Messrs. Cypher exhibited a fine batch of C. Fairrieanum at the Royal Horticultural Hall, displaying about a hundred flowers. This, however, was only part of a batch that flowered finely at Cheltenham, and it is the whole batch of this little orchid that is figured herewith. In the picture there are no fewer than two hundred blooms, the largest number, no doubt, that has ever yet been seen together under cultivation. The species shows some amount of variation, and it is being used largely for hybridising purposes. Remembering the success that has attended the use of C. Fairrieanum and its progeny as parents, there is an excellent promise for future successes.

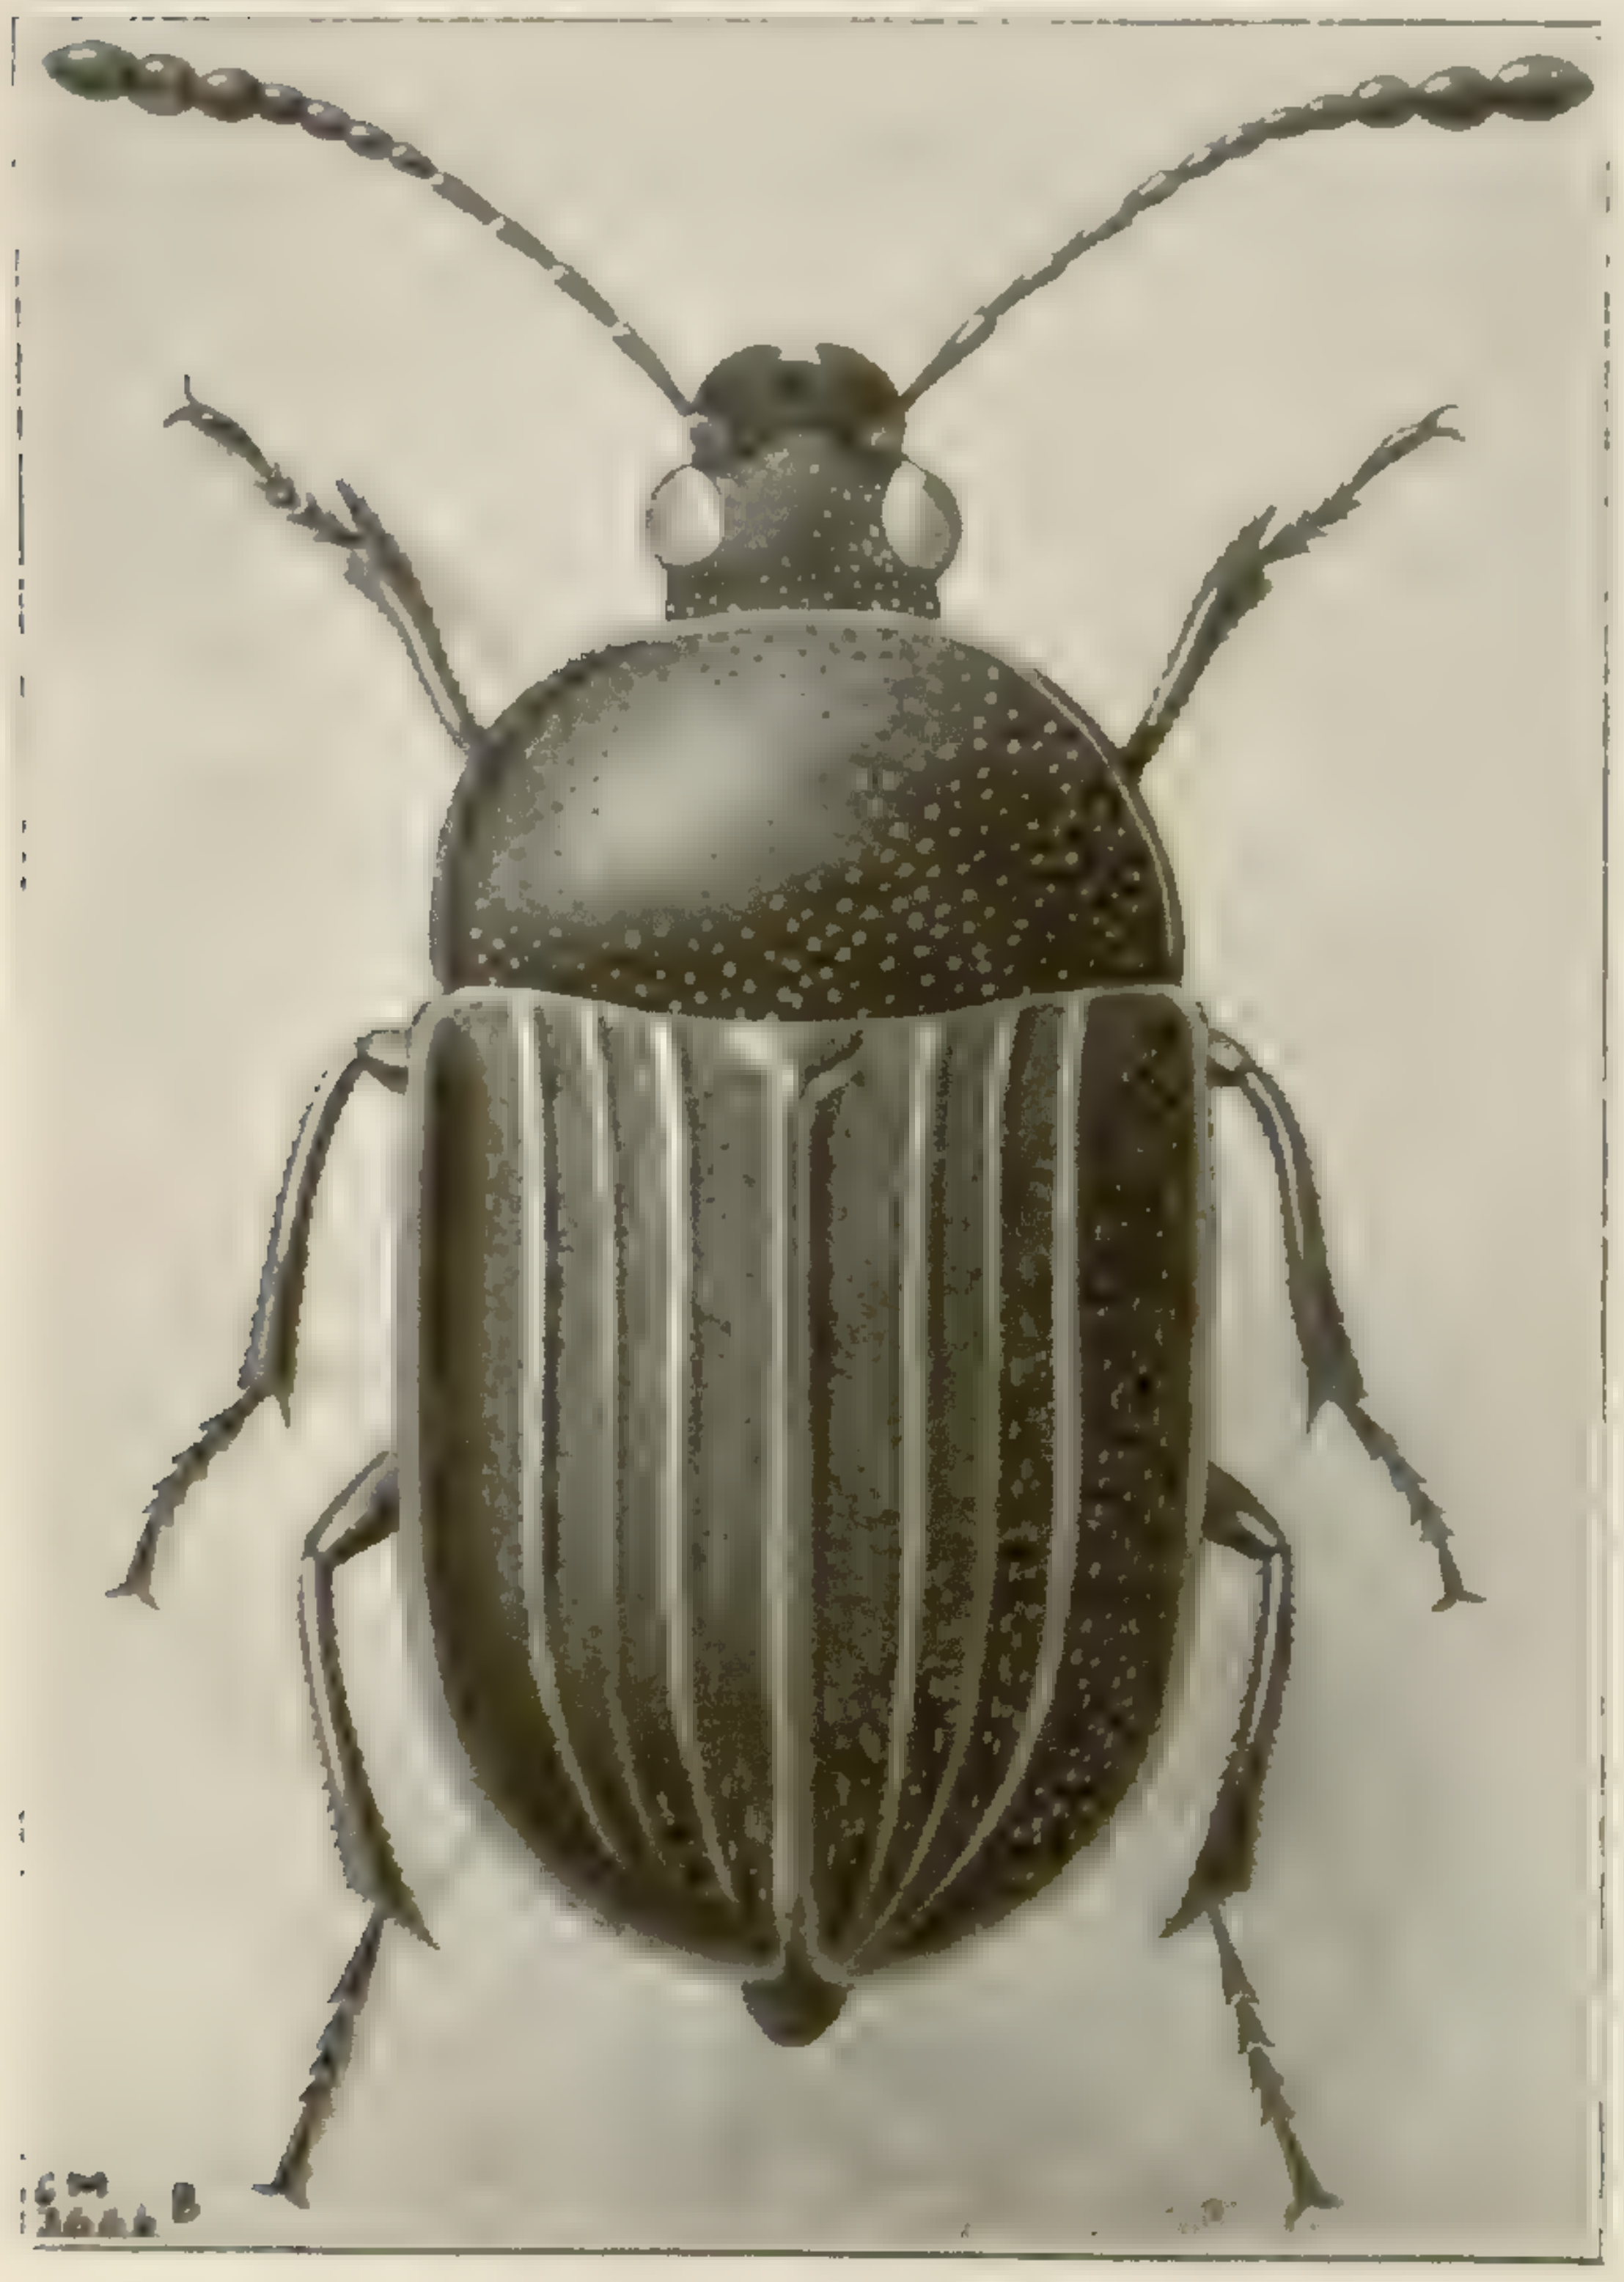
FINE GROUP OF CYPRIPEDIUM FAIRRIEANUM AT MESSRS. CYPHER AND SONS' NURSERIES, CHELTENHAM.

HARDY FLOWERS are always popular, as they make the garden bright and attractive, and require but little attention. All the information required for their successful culture is given in Easily Grown Hardy Perennials, by G. H. Vos. Price 5s. net, by post in box, 5s. 6d., from W. H. and L. Collingridge, 148 and 149, Aldersgate Street, London.

BEETLE REVELATIONS.

Gardeners suffer more from the depredations of beetles and their grubs than they are in the habit of suspecting, and more than one reason is accountable for this partial oversight. I do not, of course, infer that they are in the dark concerning their destructive attributes, but my meaning is that a far greater extent of damage may be traced to this kind of insect than believed, which is frequently considered to be the pernicious work of other creatures, especially slugs, the latter often wrongly being regarded as the most intolerable object of life it is possible to encounter. As an interlude it may be said that some species of slugs are strictly carnivorous, feeding exclusively on their herbivorous companions, worms and insects, and should therefore be encouraged.

It is customary for beetles to fly principally during the night time, so that unless they are encountered by chance, or deliberately sought for, it is seldom that they are seen. I daresay that an entomologist, with his knowledge of these and other facts, and with his methods of procedure in regard to capture, could surprise a gardener by producing an abundance of these creatures even in areas where they are supposed to be scarce. Over eighty thousand different species have been described. Note that, 80,000, each different from every other one; and yet hundreds more of various kinds are believed to have escaped the hunters after truth.



THE BEET BEETLE (SILPHA ATRATA)
Much magnified.

Out of this enormous number I select a mere half-dozen for description; but even these six are capable of inflicting immense loss when their presence and progress is unheeded or unchecked. The range in sizes of beetles is very noticeable, graduating from tiny objects, which could be pushed through fairly large pinholes, to huge things which, with their legs outstretched, can cover a human hand. Observe the magnified portraits which I have carefully drawn from life. It will be seen that as objects full of elegance and ornamental detail they have a charm and attraction, although they are pests.

Beet Beetle.

It is lucky for the gardener and other cultivators that the majority of beetles are carnivorous, feeding either on living insects and small forms of life, or else on dead animal matter, both in the winged and grub states. The beet beetle belongs to this section, but only during its mature existence does it indulge in flesh diets. This specimen is quite a giant besides the others in this set, being two-thirds of an inch long, polished black, and with a series of ribs along the wing covers.

Sometimes it will favour vegetation, but only when the latter is decaying. This point bears an importance for us, and should be noticed. Its grubs play havoc with beet and mangels, feeding on them chiefly at night time, and as the leaves decay in consequence of attack the winged beetles may be induced to remain and feed on the rotting vegetation, especially if animal matter is scarce, and thus mislead the onlookers into the assumption that they are the direct, instead of the indirect, cause of the mischief. This fact is especially regrettable, because these beetles are known to be great feeders on slugs and caterpillars, and would thus become a source of benefit sometimes, instead of the reverse. Gardeners who do not grow beet should remember these details, and befriend the beetle, or not, as conscience concerning their neighbours dictates. Other growers in the vicinity who favour beet might suffer, but—well, I am not moralising.

The grubs run about on six legs, and have a strange resemblance to woodlice.

The paraffin and soap emulsion could be employed for the eradication of the grubs, but the most valuable precaution will be to avoid the accumulation of foul-smelling manures, especially those derived from the slaughter house, which are liable to coax these beetles in large numbers to the spot.

They undergo their chrysalis transformation in the soil, and come forth perfect during the autumn, hibernating throughout the winter, after which they lay their eggs in the spring.

Clay-coloured Weevil.

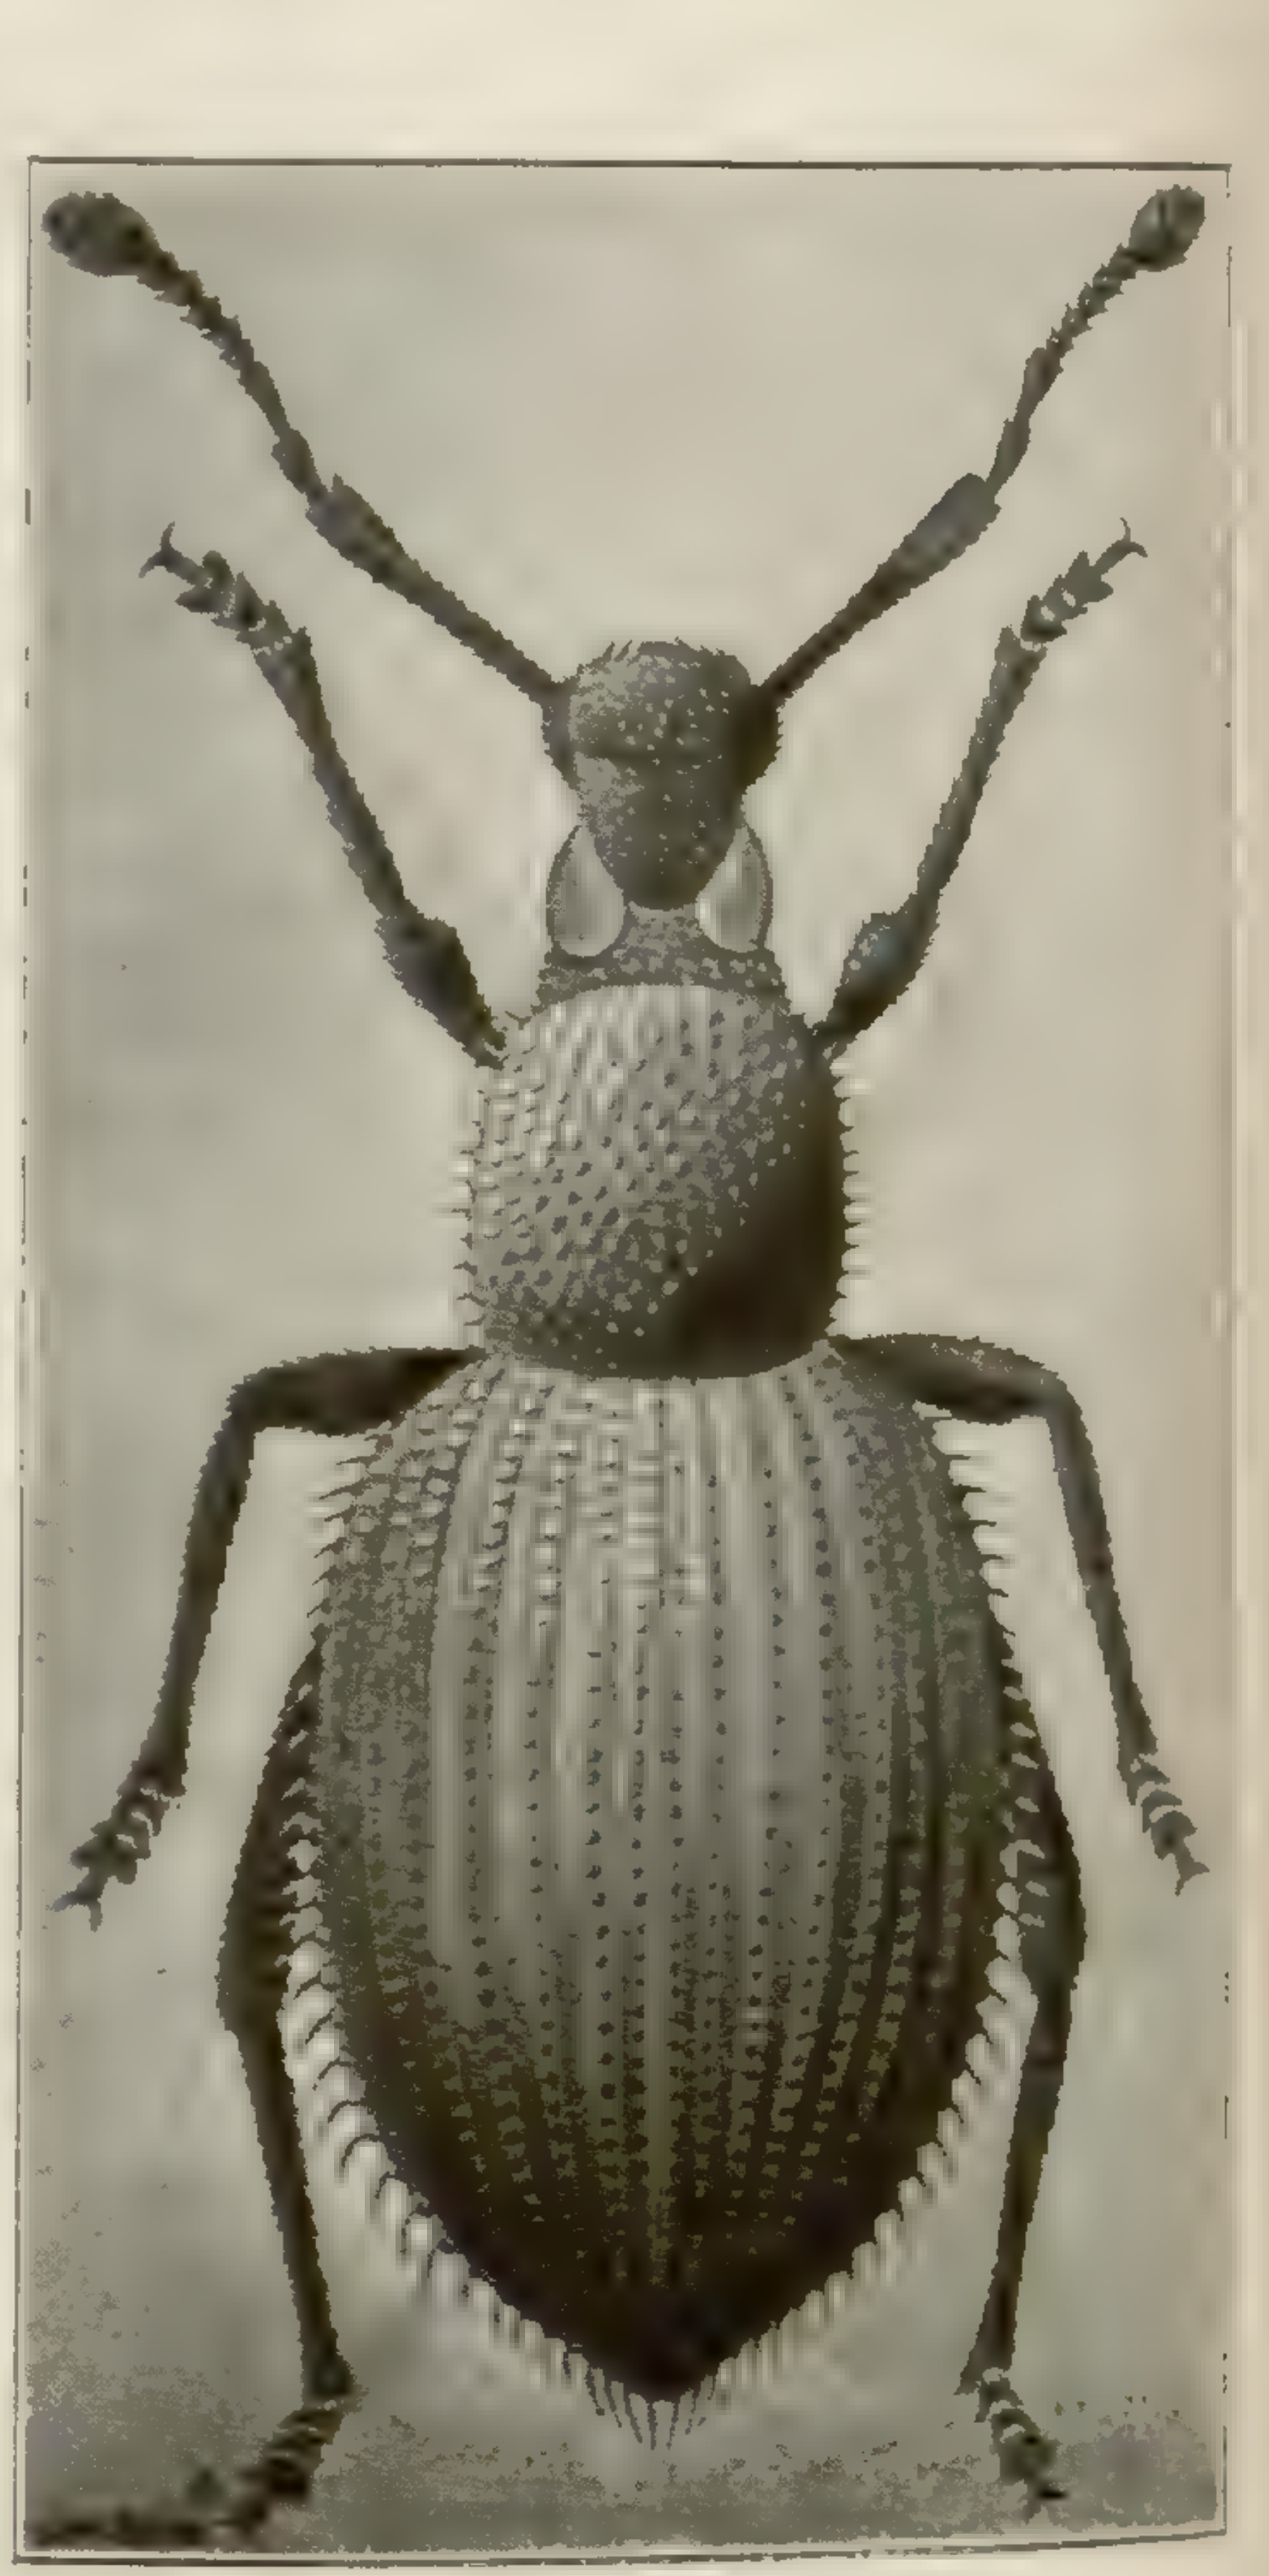
The clay-coloured weevil and its near allies are among the very worst foes that the gardener has to contend with. The first is about a quarter or a third of an inch long, and looks like a tiny ball of clay when it is on the rough ground, although magnification will bring out many picturesque details. These weevils are adepts at feigning death, so that the reader must be sceptical concerning appearances, the more so because of the amazing fact that they are so tenacious of life that little short of boiling water will destroy them. Even pungent, penetrating turpentine will only cause them to become fidgety for awhile. Powerful odours and extremes of climate are alike ignored by them, so that fumes in greenhouses cannot eradicate them effectually.

They feed on nearly everything, but favour fruit trees, and seem especially in love with vines. It is not the fruit or flowers, however, which they seek, but the tender leaves and juicy shoots, which, by being nibbled curiously in a circular manner, are frequently nearly divided into detachable pieces, thus preventing the due flow of the rich sap to sustain the forming fruit.

Roses, plums, pears, raspberries, strawberries, peaches, peas, beans, turnips, ferns, and flowers—all are alike liable to be indiscriminately attacked by the clay-coloured weevil and its mates.

While the perfect beetles are so badly industrious among the open portions of the vegetation, their grubs are busy at the roots, so that together they may cause disaster. These grubs are legless, creamy-white, and covered with brownish tufts of hairs. They go to a depth of from two to four inches in the ground to pass through their transformations.

The beetles become very active at night, having probably spent their time elsewhere during the day. Therefore, when the su has set the most favourable opportuniti for their capture are presented. All wearying trouble of the kind involved would b amply paid by results. Tarred cloths an papers should be placed in convenient situations, and branches, etc., steadily shaken, causing them to fall. By suddenly introducing bright lights into their haunts they are startled, and instinctively fall into any traps prepared, such as open umbrellas, whence they can be quickly transferred to



THE CLAY COLOURED WEEVIL
(OTIORHYNCHUS PICIPES.)
Much magnified.

pots of carbolic acid or some other destru tive medium. It would be preferable "light up" in their vicinity instead carrying a sheltered lamp or lantern fr the house, which might gradually wa them. A policeman's bull's-eye lan suddenly turned on to their abode wo work wonders in shifting them. They a among the very few beetles that are win-less, so that there is no chance of th flying away when frightened.

Soot, lime, or salt should be worked the grub-infested soil, but if an atta happens to be exceptionally severe no but the complete clearing out and burnin of it all would be of any avail, to be followed by replanting in properly prepared soil.

As the beetles conceal themselves i various odd crannies during daylight, th cracks in garden walls, vineries, and fe should be either well inspected for sepa capture of the insects, or be plugged u

Summer is, of course, the time in w to find their eggs.

JAMES SCOT

(To be continued.)

SUMMER BEDDING.

It would be well before the season is too far advanced to decide definitely what kind of plants should occupy the flower beds during the summer months, and how they should be arranged, so that the quantity required may be prepared accordingly.

There are not many gardens where tender plants alone are employed, for though there is a great variety of such useful subjects, they take up far too much room during the winter months for the amount of glass available for their protection. But there are many hardy and half-hardy kinds that are quite as useful, and these may be used to advantage, providing the stock is increased to the requisite number.

Lobelia cardinalis.

There are but few plants that make a greater display during the latter part of the summer than Lobelia cardinalis. Though this is not hardy in all places, stock plants may be wintered in a cold frame, and as soon as they commence to grow, which they will do in most places by this time of the year, they should be pulled to pieces, and each piece planted singly in light rich soil either in boxes or in a cold pit or frame, where, if treated liberally, they will make fine sturdy plants that will lift with a good ball of earth and roots by the time the flower beds are ready for them. During the summer months an abundance of moisture and an open situation suits them admirably, but to be effective they should be planted in bold groups or used as dot plants about two feet apart in large beds.

Calceolaria amplexicaulis.

Another useful plant is Calceolaria amplexicaulis, as its clear canary-yellow flowers are very attractive. Nothing could be more useful in its way than this, and few plants are more easily propagated. Cuttings inserted in a cold frame in the autumn will make fine plants by the following spring. Like the lobelia they require a rich, moist soil, and then, given liberal treatment through the summer months, they are sure to give satisfaction. The reason so many fail with this plant is because they do not transplant early enough, or allow sufficient room. They should be transplanted as soon as well rooted, which will be in February, if the cuttings were inserted in a cold frame in the autumn. If planted in light, rich soil, about six inches apart, where they can be afforded the protection of a cold frame until re-established, they will make fine sturdy stuff by the time it is safe to transfer them to the open ground. To allow them to become the least drawn in their cutting beds is a great mistake, and one of the chief sources of failure. In good soil these plants will grow a couple of feet through by the autumn, so they ought to be allowed space accordingly.

Blue Salvias.

There are but very few blue flowers that can approach Salvia patens, and as a stock is so easily grown, taking up but little room in winter, those whose glass accommodation is limited may grow it to perfection. The old roots, taken up in the autumn and stored away like the dahlia, will give an ample supply of cuttings if placed in gentle heat at the present time. These cuttings will make strong plants by the time it is safe to plant them out. There is another kind, known as S. Pitcheri, which, with us, grows to the height of four feet or more, but does not flower until late in the autumn. For several years this has been left out through the winter and has grown up quite strong again each succeeding summer.

Cannas.

The improvement in cannas during recent years has caused them to become very popular for summer bedding. The roots may be stored away during the winter in a very small space. The rich bronzy foliage of some of the varieties, too, is very telling, especially when seen in bold masses. As is well known these plants are readily increased by dividing the roots in spring and growing them in a warm house until it is safe to transfer them to the flower beds. They like rich soil, with an abundant supply of moisture during the hot weather in summer; given these, and strong healthy plants when put out, they will not fail to give satisfaction.

Swainsonias.

Swainsonias, both white and purple, make grand subjects for summer bedding. They may be either used as dot plants amongst dwarfer things, in groups by themselves, or kept pegged down so as to form a carpet for other and taller plants. If employed in this latter manner it is preferable to use young plants rooted in a cold frame in the autumn in the same way as recommended for calceolarias, or in heat early in spring. Either method will answer equally well, though the former gives the least trouble. Plants may also be raised from seed sown early in spring, but seedlings do not flower so soon as plants raised from cuttings. The plants, when rooted, should be potted, and grown freely until it is safe to transfer them to the open ground. Old plants may be wintered in cold pits or in a house where the frost can be excluded. In some districts the swainsonias will withstand the severity of our winters, and though cut down to the ground by the frost will grow up again strongly the following spring, and make growths from ten to twelve feet in length by the following autumn. It is, however, the safest plan to winter the old plants in cold pits, when, if more are required, these may be used to propagate from.

Variegated Grasses.

We have still another class of very useful plants, such as the variegated Eulalia japonica, E. zebrina, etc. These are readily increased by divisions, and if potted up and grown in gentle heat they will make useful plants for mixing with other subjects, as their light, elegant foliage makes them very attractive. Dactylis glomerata elegantissima should also be propagated now by dividing old plants and planting the divisions in a cold frame until established, they can then be transferred to the flower beds at any time when required.

H. C. Prinsep.

Buxted Park Gardens.

Pentstemons.—The value of these for a long-continued display of their bright flowers is becoming more and more appreciated, though still not so fully as their merits deserve. Good forms raised from seed can be selected and propagated annually in the same way as calceolarias, but where distinct colours are at once desired now is a good time to order named varieties. Numerous charming shades are procurable, and a few good varieties are Crimson Gem, George Horne, Phryne, General White, Ninon de l'Enclos, Talma, Daphne, Edwin Beckett, John Jennings, Lord Lister, and others. Newbury Gem and White Newbury Gem, though not bearing such large flowers, are even more continuous bloomers, and so extremely elegant that they should be included.—E. F. Hazelton. Knowsley Gardens.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

WINTER FLOWERING CYPRIPEDIUMS.—The remarkable displays of cypripediums that have been made at the Royal Horticultural Society's meetings during the past winter, have no doubt added to the popularity of the lady's slippers. I had also opportunities of seeing some displays at the Manchester and North of England Orchid Society's meetings, and the enthusiasm shown among amateurs in the Manchester district for these most desirable plants has undoubtedly given the society a renewed lease of vitality, thus illustrating a useful fact, that, in the winter-flowering cypripediums, we have subjects that can be successfully cultivated in a district where plant life in general exists under unfavourable atmospheric conditions.

RENEWAL OF COMPOST.—The present is a season at which repotting may be attended to. Such species as C. Fairrieanum, C. Charlesworthi, C. Spicerianum, and the numerous sections of C. insigne, do not require annual repotting, so that providing there is ample root room, or the plants have not outgrown their pots, they should be disturbed as little as possible. All dead and decaying leaves should be removed from the base of the growths, which will permit perfect freedom for the new growths and roots when they make their appearance, and any decomposing moss or potting material should be removed and fresh compost added. There are many hybrid winter-flowering cypripediums that resent being disturbed, particularly those which have C. Fairrieanum as one parent. I have frequently remarked that the best flowers of this section are generally produced on plants that have not been repotted the previous year. Large specimen plants, where potting is required, should be carefully turned out of their pots, so that the least possible damage may be done to the roots. Where roots have become firmly attached to the sides of the pots, they will be found much more easily removed if they have a thorough wetting previously.

REPOTTING.—When the plants are turned out of the pots carefully remove all potting compost and cut away dead and useless roots. Plants that have become hollow in the centre should be separated and the growths placed so as to make up any deficiency in this respect. The pots used should be of liberal size for robust rooting kinds, thus allowing sufficient rooting space to carry the plants for a season or two without repotting. The pots should be filled to one-third their depth with clean drainage, or, where bracken roots are used, the pots may be filled to one-half their depth with the roots chopped to convenient size. The potting compost we use is of one part turfy loam, the remaining two parts consisting of fibrous peat, chopped sphagnum moss, and sufficient coarse sand and finely-broken crocks to render the whole porous. For smoky districts less loam should be used in the potting compost. The light is so poor during the winter months that it is a very difficult matter to prevent the plants remaining wet for too long a period, where a heavy potting compost is used. After potting give rain water through a moderately coarse rose. All freshly-potted plants must be carefully shaded from strong light and the atmsophere should be kept humid.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

ACALYPHAS may now be propagated easily from cuttings of young growths, or the stems may be cut into eyes. They succeed best if placed singly in small 60-sized pots filled with a sandy compost.

Plunge the pots in a bottom heat of 70 deg.; keep close, moist, and well shaded until root action has commenced. Before removing the plants from the propagating case gradually harden them by carefully admitting light and air. The plants should at all times be accorded a position near the glass, but if necessary give them shade during the hottest part of the day. Plants raised early in spring and grown on in five-inch or six-inch pots make valuable decorative subjects for autumn use. If larger specimens are desired take out the points of the plants as soon as rooted and continue pinching out the growths until the required size is secured. A careful look-out must be kept for red spider, which appears to be partial to acalyphas, and if allowed to remain on the foliage it will quickly disfigure them.

ALOCASIAS.—Where ornamental foliage plants are appreciated the alocasias are almost indispensable; they are amongst the finest and most distinct of all our stove foliage subjects. In order to be successful with alocasias they must receive abundance of heat and atmospheric moisture; without these two essentials they do not develop their true form and character. They can be readily propagated by the removal of suckers or by division of the underground stem. The present time is a very suitable one for propagating alocasias, as old plants will require attention. Alocasias will succeed if potted in the same way as orchids. They require ample drainage, and the crowns should be packed well up above the pot rim with sphagnum and the best fibrous peat, adding a few lumps of charcoal and broken crocks. After potting the pots should be plunged in a bottom heat of 70 deg. to 75 deg. Shade at all times from the hot sun, but allow the plants to enjoy a light position. As the season advances some of the larger specimens will require larger pots. During their growing season syringe them thoroughly and sponge the leaves occasionally to keep them clean and healthy. When the pots are well filled with roots an occasional watering with weak liquid manure or clear soot water will be of great advantage.

BEGONIA GLOIRE DE LORRAINE.—Cuttings should be rooted, and for this purpose secure growths from as near the base of the plants as possible, and place them singly into small thumb pots filled with a mixture of cocoanut fibre refuse, or leaf-soil, and silver sand in equal parts. For the successful culture of this begonia the soil must not be pressed firmly about the roots. When repotting the plants care must be exercised with the roots as these are of a delicate and tender nature. The soil used for the final potting ought to be of an open and porous nature. Throughout the season the main object ought to be to keep the plants steadily growing. They succeed best, according to my own experience, when grown in a small stove where a temperature of about 60 deg. can be maintained. For general decorative use those of a pyramidal shape, tied to a central stake, are the most serviceable.

AGLAONEMAS.—These may now be easily propagated by division of the roots. They are very serviceable as an edging for the stove, and colour best when grown in small pots and regularly watered with clear soot water or weak liquid manure.

FITTONIAS are also most useful plants and of easy culture. Good plants are very soon obtained if from four to six cuttings are rooted together in small pots.—JOHN DONOGHUE, Bardon Hill Gardens.

FRUITS UNDER GLASS.

CUCUMBERS.—With increasing light cucumbers will grow apace and should be given every encouragement to ensure early returns; as soon as the young plants get hold of the fresh soil more water may be given. If fruits are required immediately let one come on the first shoot and then stop the shoot. Cucumbers need plenty of heat and moisture and not much air; cold draughts should be avoided or mildew will appear.

FIGS IN POTS.—As the plunging material sinks renew it or fill up the bed with leaves and stable manure. Thin the fruits if there are too many for the strength of the tree. St. John's will carry more fruits than Brown Turkey or Violette Sepor. The fruits being now a good size and the pots or tubs full of roots weak liquid manure may be given. Place some strips of turf round the edge of the pots to form a deeper basin for holding water. The shoots may be stopped at the fourth or fifth leaf. At the flowering stage syringing must be reduced, especially on dull damp days; after this stage is passed the top heat may be increased and syringing should be regularly done to keep down spider.

BANANAS.—These should be tubbed or planted out, as the case may be, without delay. Some good fresh turfy loam should be selected (and this should have plenty of fibre in it), and mixed with half-inch bones, old mushroom bed manure, and a good sprinkling of soot, and plenty of lime or plaster rubble. Large, sound paraffin tubs cut down to three-quarter size make excellent receptacles for bananas; they should be charred inside before use. When tubbing leave plenty of room for water. Plants that are expected to fruit this summer should be top-dressed liberally with good turfy loam and manure. Place some zinc round the inside of the tub, about 12 inches wide, as this will leave plenty of room for water, because, through the summer too much water can hardly be given. Bananas planted out give much less trouble and better fruits are obtained; the soil in the bed can be renewed at intervals. One sucker to each plant is sufficient to retain. Suckers that were taken off those plants that fruited last season, and were put in ten-inch pots, should be ready for a good shift.

ORCHARD HOUSE.—If very bright weather occurs when pears, apples, or cherries are in bloom, it is as well to run a piece of shading over the house about midday, otherwise the flowers do not have sufficient time in which to set. Bees are excellent fertilisers and save a lot of hand work. Apricots and plums generally set well, and a damping overhead with tepid water when they are in bloom will help them. Ventilate the house at all times if possible, and before the trees come into flower they should have a good watering. Apricots are practically a failure outside in our heavy soil, but in the orchard house they always ripen off a good crop.

EARLY VINERY.—Before the vines come into flower, if the border is at all dry, give a good supply of tepid water, choosing a bright day for the watering and raising the temperature slightly. Most of the shoots will be tied down now, so remove small and badly placed bunches. The flowers should be fertilised with a soft brush, and both brush and pollen should be perfectly dry; keep the house a little drier at this stage, and admit air all the time, weather permitting. On bright mornings and all favourable occasions ventilation should keep the house sweet and the foliage a good colour; warty leaves are the outcome of bad ventilation and stuffy houses.—A. B. WADDS, Paddockhurst Gardens.

THE KITCHEN GARDEN.

PARSNIPS.—If these have not already been sown they must now receive attention. The ground should have been deeply dug, so that the roots can penetrate it easily. When the roots are required for exhibition it is most necessary, and especially so on heavy clay soils, to make holes 2ft. deep with a bar, filling them up with lighter soil such as old potting compost with a little new loam added to it. The celery ground is an ideal place for this and most root crops; allow 15 inches from hole to hole, and 18 inches between the rows. The Student and Carter's Maltese are two excellent varieties.

ONIONS form one of the most important crops and one that requires to be sown early, and for this the soil should be in a nice workable condition. If the ground intended for onions was trenched and manured some time ago it will now break down easily and make a good seed bed. If the soil is at all light it will require treading before the seed is sown and also after. Draw drills 15 inches to 18 inches apart, sow the seeds evenly, and do not cover them too deeply in the drills. In some gardens onion maggot is very troublesome, and when this is the case it is a good plan to scatter a little flowers of sulphur along each drill before the seed is put in.

VEGETABLE MARROWS are always appreciated in the dining room as early as it is possible to get them, therefore a few seeds of Moore's Cream should be sown at once, placing one seed in a three-inch pot and putting them in heat. When they have germinated they should be kept near the glass, and afterwards hardened off a little, and be planted on hillocks of loam over a half-spent hotbed, syringing them and closing the frame up with a little sun heat in the afternoon.

POTATOES IN CLAMPS.—These should now be examined, removing all diseased ones, and selecting suitable sizes for seed purposes. It is not wise to have sets too small, about 2oz. in weight is a suitable size. If these can be spread out thinly in a frost-proof shed or in boxes they will make nice strong sprouts by planting-out time. The tubers that are left for eating should be kept covered up to prevent them greening.

EARLY POTATOES.—The crops that are coming on for succession in pots and frames will want attention in the way of top-dressing or earthing up, if they have advanced seven or eight inches in growth. More air must also be given as the sun advances in power. A little sprinkling of bone-dust or basic slag given at this stage helps them on wonderfully.

PEAS.—Such varieties as Telegraph and Early Giant may now be sown, as their yield is generally superb, and they are of splendid flavour when cooked. Quite Content is a pea of exceptional size, of first-rate flavour, and most useful for the exhibition table. But it must be given plenty of room and not too rich a root run.

LEEKS.—The main sowing of these should be made either in lines or broadcast on a seed-bed. If they can occupy the same kind of site as the onions this will suit them well; but they must be transplanted early, not leaving them in the seed-bed too long, or they will become weak and stunted, and more apt to run to seed later on.

GENERAL REMARKS.—On rainy days, when the men cannot work in the garden, pea and bean sticks should be sharpened and trimmed ready for use. Large wooden labels may also be made and painted ready for the crops. Keep up a succession of French beans by making a sowing every fortnight or three weeks, according to the demand.—T. W. BIRKINSHAW, Hatley Park Gardens, Sandy.

CALANTHES.

Your correspondent, Mr. Mayne, of Bicton, wisely directed attention a short time since to such attractive and useful midwinter flowering subjects as Calanthe Veitchi, C. vestita rubra oculata, and C. v. lutea oculata. They are all of comparatively easy culture, and yield a wealth of choice flowers, even when growing with other subjects, as Mr. Mayne describes. It gives me great pleasure to endorse all he has written, and I should like to supplement what he has said with regard to these beautiful and meritorious orchids.

There can be no question as to their usefulness for supplying cut sprays and for decorative purposes generally in the warm conservatory and corridor, and also in the mansion. We have frequently had plants in the house during the festive season fully a fortnight (without any apparent injury to the pseudo-bulbs). When associated with ferns and other fine foliage plants their long and elegant spikes of attractive flowers are very effective. Our plants are both rested and grown suspended from the roof over the centre path of a span-roof pine stove, where the spikes have no restriction in spreading over the pines when unfolding their blooms. These, with two rows of Poinsettia pulcherrima on the back wall on either side of the path, had a warm and brilliant effect on the cold, dull days of December. The somewhat warm and dry heat of the pine house, when syringing has been discontinued, is favourable to the development of the flowers of the calanthes and the bracts of the poinsettias.

The calanthes are grown in 24-sized pots, four in each, and each bulb is allowed one spike. They have a compost consisting of fibrous loam and peat, with a little cow dung and a small quantity of chopped sphagnum, charcoal, or broken crocks to keep the whole porous. The pots are filled to about one-third of their depth with crocks. In our case we find the plants grow away better when the young growths are somewhat advanced before division and potting takes place. Very little water is required until the roots have taken to the new compost. We also find a top-dressing of moderately fresh cow dung beneficial when the spikes are in process of development, and water is entirely withheld when the spikes are nearly developed, as Mr. Mayne advised. It would be interesting to know the length of spike and number of flowers on, say the longest spike grown by Mr. Mayne, or others. I found our spikes last season both of C. Veitchi and C. vestita rubra oculata averaged 3ft. in length with thirty to forty flowers, but we have had them sometimes nearly 4ft. long, and, once only, 4ft. 6in. long, with forty to fifty flowers. Years ago the late Mr. Petch, when gardener to the late S. Mendel, Esq., of Manchester, had spikes of C. Veitchi, 6ft. in length, and bearing about fifty flowers each. I was much interested in the illustration you recently gave of a group of specimens of this hybrid grown at Buxted Park, and I am anticipating with considerable pleasure Mr. Prinsep's account of his practice.

S. Pragnell.

Broomfield Lodge Gardens, Chelmsford.

M. P. Nabonnand, the highly successful and well-known raiser of roses, has been promoted to the rank of Officer in the Order of the Merite Agricole.

THE FRANCO-BRITISH EXHIBITION.

On the occasion of a recent visit to the Franco-British Exhibition, which is creating so much interest both in this country and in France, we were much impressed by the rapidity with which advances are being made in all directions. An immense amount of work has to be accomplished before the opening in May next, but the progress that has been made since we visited the grounds in December last has been such as to suggest that little beyond a few finishing touches will be necessary on the eve of that function. Especially noticeable is the progress that has been made with the numerous palatial structures that will form so striking a feature of the exhibition, and the work of laying out the gardens. Many of the former are now rapidly approaching completion, and a much better idea can be obtained of the scope and magnitude of the exhibition than was possible two months ago. The information then available was sufficient to show that it would be comprehensive, and that the representation of the arts, sciences, and industries of Great Britain and her Colonies and Dependencies, and of France and her colonial possessions, would be of exceptional interest. But now it can be seen that the twenty or more palaces or halls provided for the display of the varied products are of vast proportion, handsome in elevation, and so arranged as to produce in combination with the numerous pavilions a striking and extremely beautiful effect. The planting of trees, the laying of turf, and other work that has been done suggests that the gardens will form an admirable setting to the handsome buildings, and be a great source of attraction to the visitors.

It is gratifying that both agriculture and horticulture should have had important positions assigned them in the comprehensive scheme formulated by the exhibition authorities. The group devoted to horticulture, arboriculture, and forestry, comprises appliances and processes used in horticulture and arboriculture; seeds and plants for gardens and nurseries; fruits and fruit trees, pomology, and cider making; trees, shrubs, ornamental plants and flowers; greenhouse and hothouse plants; appliances for gathering wild crops and products obtained; appliances and processes used in forestry; and products of the cultivation of forests and of forest industries. The classes provided in this group are 49, 50, and 51. The first of these is set apart for appliances and processes used in arboriculture—special instruments for gathering, preparing, testing, and preserving seeds; tools and appliances used in tree culture and in the forest industries, tree measuring instruments; preserving timber by creosote and other substances; examples and processes; prunings, good and bad, and their effects; malformation, curious growths of branch and root; damage by fungoid pests, insects, animals, storms, frost.

The second, for products of the forest and of forest industries—collections of fruits, seeds, cones; specimens of indigenous forest products, home-grown timber cut into boards and transverse sections, giving age and conditions of growth; comparative exhibits of timber grown under various conditions; woods for cabinet work, building, staves, cricket bats; wooden gates and fencing (not painted or varnished); basket work, wattling; tan-bark, resinous substances.

The third, for photographs, pictures, models—photographs of specimen trees and groups of trees, new or rare trees suitable for cultivation in the British Isles; also showing operations in transplanting large trees, and various operations in forestry, such as thinning (before and after), coppicing, felling, removing timber and sawing; forest and nursery topography, maps, plans, books, charts showing imports of timber; of insects and fungi injurious to trees and their effects.

There will be three horticultural exhibitions in the course of the season, and the dates of these are June 2 and 3, July 16 and 17, and September 23 and 24. The officers and committee of the horticultural and arboricultural section are as under: President, the Right Hon. Lord Blyth of Blythwood; chairman, Lieut.-Colonel D. Prain, F.L.S.; Mr. F. J. Baker, A.R.C.S., Colonel T. Bailey, R.E., F.R.S.E., Mr. Edward Beckett, V.M.H., *Mr. W. J. Bean, Mr. W. A. Bilney, Professor Boulger, M.A., Mr. George Bunyard, V.M.H., Mr. F. J. Chittenden, Mr. William Cuthbertson, Sir Thomas R. Dewar, Mr. J. R. Diggle, *Mr. H. J. Elwes, F.R.S., *Mr. J. S. Gamble, C.I.E., Mr. John Green, *Dr. A. Henry, M.A., Professor Keeble, M.A., the Right Hon. the Earl of Kinnoull, Sir Trevor Lawrence, Bart., K.C.V.O., Sir John D. Llewelyn, Bart., Sir Herbert Maxwell, Bart., Mr. H. B. May, *Mr. J. I. Michie, Mr. G. Massee, V.M.H., Mr. A. H. Pearson, Mr. Spencer Pickering, F.R.S., Sir Patrick Playfair, C.I.E., *the Right Hon. Lord Redesdale, G.C.V.O., K.C.B., Major Leslie Renton, M.P., Mr. T. A. H. Rivers, Mr. T. J. Salmon, Mr. Edward Sherwood, Professor William Somerville, Mr. Arthur W. Sutton, V.M.H., Mr. H. R. Sutton, Mr. F. V. Theobald, Mr. J. H. Turner, Rev. William Wilks, and the secretary, Mr. J. A. Alexander, F.B.S.Edin., F.R.G.S. The members of the Forestry Sub-committee are indicated by an asterisk.

One of the most attractive and useful of the many handsome buildings in the exhibition grounds is that in which the Garden Club will be located. The club will be opened concurrently with the opening of the exhibition, and should be a great convenience to those who visit the exhibition at frequent intervals, whether for pleasure or business purposes, and appreciate such advantages as club life is able to afford.

EPPING FOREST.

The report of the Epping Forest Committee on the work of the past year is highly satisfactory. The question is dealt with at some length, and a full explanation of the policy adopted is given. The Consultative Subcommittee have, it is stated, visited and carefully inspected the various woods needing attention, and have superintended the marking of the trees to be felled. The principle upon which the committee have always acted has been the preservation of the best trees, and the removal of ugly and inferior ones, and this has resulted in a very great improvement in the growth of the trees, and the general appearance of the forest. The more valuable ones, whether singly or in groups, have been given space for their full development, and no trees have been cut down because of their value for sale. In this connection it is of interest to note that the outlay on the thinning exceeds the proceeds by £70 last year.

Difficulty in disposing of some of the thinnings has been, it is stated, experienced, and consequently the committee have reverted to the ancient practice of charcoal burning, an arrangement having been made with Mr. Firminger, whose family have carried out charcoal burning in the forest for more than a century, for converting a portion of the thinnings into charcoal.

A census of the deer was taken recently. In the morning 112 fallow deer were counted in the forest, and in the evening 126. The roe deer in various coverts adjoining the forest numbered 32. This shows a diminution of no fewer than 45 fallow and 3 roe deer since the census of February, 1906—a matter which is occupying attention.

In regard to finance, the committee state that in October, 1906, they estimated the expenditure for 1907 at £5,800, and the income at £2,600. The total expenditure was, as a fact, £6,034 3s. 5d., and the total income £3,051 2s. 2d., leaving the sum of £2,983 1s. 3d. only to be provided out of City's cash.

M. H. Martinet, the editor of our excellent French contemporary "Le Jardin," has been promoted to the rank of Commander in the Order of the Merite Agricole.

NEW BOOKS.

◆

EIGHTH REPORT OF THE WOBURN EXPERIMENTAL FRUIT FARM.

By the Duke of Bedford, K.G., and Spencer N. Pickering, F.R.S. (The Amalgamated Press, Lim., Carmelite House, Carmelite Street, London, E.C.) Price 2s. 6d.

There can be no question as to the seven previous reports on the important work that is being done at the Woburn Experimental Fruit Farm having been of much interest and extremely useful to those who fully appreciate the value of scientific methods in fruit culture. What is true of the previous reports applies with even greater force to the eighth which is now before us, and, were it necessary to institute comparisons, we should be inclined to say that it will be found of greater practical value to the general body of fruit growers than either of its predecessors. Comparison, however, is quite unnecessary, and now as expressing our appreciation of the value of the report, it will suffice to say that we regard it as an extremely valuable contribution to the literature of plant pests with which fruit growers have to contend. The subjects with which the report deals are Bordeaux mixture, lead arsenate, emulsions, mussel scale, moss and lichen, apple sucker, adhesive power of lime-washes, caterpillars, aphis, apple mildew, woolly aphis, apple leaf spot, and the nature of the action of insecticides. These do not embrace all the subjects that have to receive attention in keeping fruit trees free from insect and fungoid pests, but they form a substantial list, and each one is dealt with so fully on scientific lines that the reader is placed in possession of all that it is necessary to know in the preparation of the insecticides and fungicides of the most importance to fruit growers.

In the introductory chapter the authors refer to the objection that is so often taken to tables, percentages, and even decimals, and state that their aim has been to substitute as far as possible exact quantitative measurements for those more crude and unsatisfactory methods usually adopted, in which the impression produced on the mind of the observer is the sole standard by which the success or failure of an insecticide is gauged. "Actual measurement is," they say, "the soul of all science, and the study of insecticides, and, indeed, of any branch of horticulture, can never aspire to be raised to the level of a science until quantitative measurements are introduced into the methods of observation." The authors further suggest, as "there is probably no insecticide or fungicide which is actually without some deleterious effect on the trees," that "spraying, therefore, should be reduced to the lowest limits consistent with keeping the trees clean." These deleterious effects are often much more than counterbalanced by beneficial results obtained by destroying the parasite; but it is well to recognise them, and in making strenuous efforts to combat the various pests, not to use the spraying machine more than is necessary.

BORDEAUX MIXTURE.

Bordeaux mixture, one of the best known of the fungicides, and somewhat extensively used in combating the potato disease, is the first of the preparations reported upon, and here we find much information of immense value. The mixture is generally made by adding milk of lime to copper sulphate (blue vitriol dissolved in water). The proportions of lime and sulphate vary somewhat according to different recipes, but usually from four to six parts of lime are added to every six parts of the crystalised copper sulphate. The strength of the mixture recommended also varies considerably, and that known in America as the normal or 1.6 mixture, is made by taking 1.6 parts of the copper sulphate for every hundred gallons of the wash (1.6lb. for ten imperial gallons of water). In this country, owing to the tissues of the leaves being softer, a mixture of a lower degree of strength has been found preferable.

It is surprising that the chemistry of the Bordeaux mixture should not have been previously elucidated, and it is a matter of considerable interest to learn from a paper read by Mr. Spencer Pickering before the Chemical Society, and given in the appendix to the report, that the statement usually made by chemists with regard to the precipitation of the copper is erroneous. Of much greater importance is the fact that, as the result of his investigations in the laboratory, and on the fruit farm, Mr. Pickering has been able to prepare a much more satisfactory mixture than that in previous use. It appears to have been well established that the fungicidal action of ordinary Bordeaux mixture does not come into play until a week or more after it has been applied to the foliage. This, as pointed out by the authors, is a serious matter; for, not only may a delay in arresting the development of the fungus, once it has appeared, be a serious matter, but it involves considerable loss of materials, much of it being washed or knocked off the leaves during the period of inactivity. The mechanical loss of material is much augmented by the grosser particles of lime still left in the Bordeaux mixture when made in the ordinary way, for such particles are easily knocked off, and carry with them much of the valuable copper compound. The length of time that elapses between the application and the action of the fungicide as ordinarily prepared, is a great disadvantage; but, as a result of his investigation of the chemistry of the mixture, Mr. Pickering has been able to show that this can be obviated. He found that when the lime added was only just sufficient to precipitate all the copper from the basic sulphate formed, it contained only one quarter of the sulphur trixoide present in the normal sulphate, and that to get a mixture of the same efficiency we need take only two fifths of the amount of copper. This, it need hardly be said, represents a considerable saving. When using milk of lime it would not, according to the report, be possible in practice to adjust the quantity to attain this end; but it is quite simple to obtain an exact adjustment by using clear lime water. The following are the instructions for making one hundred gallons of such mixture: Dissolve 6lb. 6½oz. of crystalised copper sulphate by suspending it in a piece of sacking in two or three gallons of water, contained in a wooden or earthenware pail; take some good quicklime and slake it with a little water, and put it into a tub with one hundred and twenty gallons of soft water. Stir the lime and water up two or three times, and leave it to settle till the solution becomes quite clear, with a covering over the tub. Then run off eighty-six gallons of the clear lime water, and mix it with the copper sulphate solution. This mixture is a little stronger than the "1.6" mixture when made in the usual way with 16lb. of copper sulphate to one hundred gallons of water. To reduce it to the same strength, add eleven or twelve gallons of water. In practice it has been found that there is no more danger of scorching with the mixture made with lime water than with one made with milk of lime in the usual way.

EMULSIONS.

The report on emulsions is not less valuable, both from the scientific and practical points of view, than is that on the Bordeaux mixture. Some years since the authors, as the result of considerable investigation, prepared an emulsion-soda wash for use at the Woburn Experimental Fruit Farm, which was christened the "Woburn Wash," and used with much success. The proportion of the various ingredients was "caustic soda, 2 per cent.; soft soap, ½ per cent.; paraffin (by volume), 6 per cent." The amount of paraffin could be varied between wide limits, but no great variation was found possible with that of the caustic soda if the wash was to have a proper detergent effect in removing moss and lichen, whilst the proportion of the soap could not be increased without giving rise to difficulty in using the wash in the machine. As stated by the authors, the caustic soda and the paraffin in the wash do not combine chemically, but are still present as such, forming merely a mechanical mixture. "There was one disadvantage attaching to the Woburn Wash; the soap used to emulsify the paraffin and water is potash, or soft soap, and so, on adding the caustic soda, this is converted into hard soap, which is only sparingly soluble, and is consequently thrown out of solution as a flocculent solid. The paraffin, as a consequence, is no longer kept properly emulsified, and mixed with the soda-soap it generally rises to the surface in the form of a bulky scum. . . . This necessitates constant agitation of the mixture during use, and even under the best conditions the distribution of the paraffin on the trees is far from uniform."

The discovery, therefore, of some emulsifying agent other than soft soap, which would not be affected by caustic soda, became highly desirable. To attain this end Mr. Pickering set himself the task of obtaining further insight into the nature of emulsions, and of ascertaining the conditions under which emulsification occurs. A full account of his investigations is given in the paper contributed to the Chemical Society, which has a place in the appendix. There is also a brief sketch of the conclusions arrived at in the body of the book, and as this is of much practical importance, we regret that the length to which this notice has extended prevents our referring to it otherwise than in the briefest manner. In the course of the investigations it was noticed that when a little copper sulphate was mixed with the lime before churning with oil, an emulsion was formed quite different to that obtained by the mixture of lime and paraffin. Following up this indication it was ascertained that basic sulphate of copper—which is the substance formed when sulphate of copper and lime are mixed together—has the property of forming a true emulsion of the oil, due, it was subsequently found, to the minute particles of which it was composed. The emulsion produced is, we are told, very fine and creamy, and rises to the surface only very slowly, the slightest agitation being sufficient to keep it disseminated evenly throughout the whole bulk of the liquid. The presence of sulphate of copper in the emulsion indicates its value as a fungicide; but when no fungicidal action is required sulphate of iron, which is much cheaper, may be substituted.;

We should have much liked to refer somewhat in detail to the chapters devoted to the mussel scale and the apple sucker, but we have said sufficient to indicate the great value of the work to fruit growers, and, indeed, to all who are interested in the various pests with which horticulturists have to contend.

LAWNS.

By Sutton and Sons. (Simpkin, Marshall, Hamilton, Kent, and Co., Lim., London, E.C.) Price 1s.

We need hardly say that we are in full agreement with the authors of this elegant and extremely useful brochure in their estimate of the charm of a smooth verdant lawn, of its usefulness as a meeting place for social gatherings, and of its value for the opportunity it affords for healthy recreation in the various popular garden games. We might even go further, and say that the importance of the lawn as a setting for both the stately mansion and modest villa in this country cannot be over-estimated. Holding very decided views as to the charms of lawns in a high state of keeping, we consider it most desirable that correct views should obtain with regard to their formation and after management.

Hence the appearance of a new edition of "Lawns" is especially welcome, as an indication that increased attention is being paid to lawns, putting greens, cricket grounds, and other open spaces in which a smooth velvety turf is a necessity, and the endeavour of Messrs. Sutton and Sons to provide trustworthy information relating thereto is [illegible] fully appreciated. The book is so clear and comprehensive that we are not surprised at its remarkable popularity, and, recognising its value, we strongly recommend it to the notice of our readers.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Ninepence per line, the minimum charge being Five Shillings. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

◆

Linnean Society.

FEBRUARY 20.

At the general meeting of the Linnean Society, held on the 20th, a paper on "Wild Types and Species of Tuber-bearing Solanums" was read by Mr. Arthur W. Sutton, V.M.H., F.L.S., of which we give an abstract herewith.

At the outset of his paper, Mr. Sutton stated that this study of the wild types and species of tuber-bearing solanums dates from the year 1883, when the late Lord Cathcart, a member of the Council of the Royal Agricultural Society, suggested crossing the wild types with the cultivated potato, to obtain a race of commercial potatoes which would resist the ravages of the potato disease, Phytophthora infestans. Upon this Mr. J. G. Baker, V.M.H., made his inquiry into the various species and types of tuber-bearing solanums, laid before the Linnean Society on January 17, 1884. Lord Cathcart hoped that hybrids between the Solanum Maglia of Schlechtendahl (Darwin's potato), a native of the low-lying swampy grounds of the Chonos Archipelago, and a cultivated potato, might give rise to the desired race of disease-resisting potatoes.

Many hundreds of attempts were made to fertilise Solanum Maglia with the cultivated potato, but almost entirely without result, for the blooms of Solanum Maglia nearly all fall without setting seed. These crossings only gave one hybrid seedling, from a cross made in July, 1887, and though cultivated for the last twenty years, it has shown no superiority to ordinary potatoes.

Many wild types of tuber-bearing Solanums were experimented with during the last few years, including Solanum tuberosum, two forms from Mexico, S. polyadenium, Greenm.; S. verrucosum, Schlecht.; S. Maglia, Schlecht.; S. etuberosum, Lindl.; S. Commersoni, Dunal, received from Uruguay; S. Ohrondi, Carr.; S. tuberosum var. boreale (syn. S. Fendleri). Attention is especially called to the fact that all these wild types flower freely, and that in every case where a wild type produces fruit, it has, with the exception of Solanum etuberosum, reproduced itself absolutely pure from seed; in contrast to this, all varieties of the cultivated potato which produce seed give rise to the greatest possible variation in the seedlings, none of which correspond exactly to the parent.

There is also a striking difference in the form of the pollen-grains of the wild types of tuber-bearing solanums, compared with pollen-grains of cultivated potatoes, the former being elliptical, and the latter very irregular in form.

The paper dealt fully with Solanum etuberosum, the only wild type of which the seedlings have not reproduced the typical form, but have, on the other hand, given precisely the same variation in habit of foliage, form, size, and colour of tuber, etc., as is found in the seedlings from the cultivated potato. Although cultivated continuously for twenty years, Solanum etuberosum has never been known to produce a fruit until 1906, when one berry only was found, and from seed thus obtained twenty plants were grown in 1907, differing from each other as just stated. Reference was made to the specific name "etuberosum," given by Lindley, and to the fact that, though this name denotes an absence of tubers, small tubers are invariably formed under cultivation, and that the size of the tubers has greatly increased during the last twenty years, until they resemble those of the cultivated potato. The pollen-grains of the seedlings from Solanum etuberosum retain the elliptical form of the type, although the pollen-grains of a hybrid obtained by crossing a cultivated potato with S. Commersoni type vary greatly in form. As the S. etuberosum has given seedlings many of which more resemble the cultivated potato than the type, the conclusion is suggested that this may have been one of the parents of cultivated potatoes of to-day; and conversely, that as no other wild type experimented with has given seedlings which vary in any degree from the type, it is unlikely that either of these wild types gave rise to our cultivated potatoes. A fact of special interest and importance is stated, that during the twenty years of cultivation, no plant of Solanum etuberosum has ever been noticed as affected by the fungus Phytophthora infestans, although during the whole period it has been grown in close association with potatoes which have suffered more or less from it year after year.

The general belief that the cultivated potato owes its origin to a specific type of tuber-bearing solanum, to which Linnæus gave the name of Solanum tuberosum, is discussed, and attention called to the fact that the potatoes originally introduced into England or into Europe were certainly introduced as cultivated potatoes, and not as wild types, and also that it is at least doubtful whether in Chili, Peru, or elsewhere, any specific type of tuber-bearing solanum (apart from Solanum etuberosum) can be found which will, under cultivation, give plants at all like the potato of commerce. A brief summary of the history of the introduction of the potato into Europe is given, and a photographic copy shown of the earliest drawing of the potato, viz., by Philippe de Sivry, and sent by him to Clusius in 1589. Photographs are also shown of "Solanum tuberosum esculentum" from Bauhin's Prodromus, of Linnæus's original specimen in his Herbarium, and of a specimen recently collected in Chili.

To sum up: Although the evidence adduced is not sufficient to show that our cultivated potatoes certainly owe their origin to Solanum etuberosum, or that they have not been derived from some wild type which might correctly be considered the specific form of Solanum tuberosum, it is at least likely that S. etuberosum has given rise to our cultivated potatoes, and that a continuation of the experiments during the next few years will doubtless give interesting results, and possibly lead to definite conclusions.

Woolton Gardeners' Society.

A meeting was held at the Mechanics' Institute on February 20, Mr. J. J. Guttridge, superintendent of the Liverpool Parks and Gardens, presiding. The Chairman, in introducing Mr. F. Ker as the lecturer on "Hippeastrums," referred to the great success achieved by Messrs. R. P. Ker and Sons with these important and beautiful bulbous plants, not only in our own country, but also at the more important Continental exhibitions.

Mr. Ker gave a brief outline of the history of hippeastrums or amaryllis, and mentioned that amongst the earlier known varieties was one named Johnsoni, raised in the vicinity of Prescot. When cross-fertilising, it was advised to keep the colours together, that is, light with light, and dark with dark, for if colours are mixed the seedlings are largely pinks. A suitable temperature for raising the seedlings is from 55 to 65 degrees, with a damping overhead on all bright days. The plants should be potted as early as possible, affording larger pots as the plants advance; a light compost was recommended, of two parts loam, one leaf-mould, a little sand, and an addition of Clay's Fertiliser. The bulbs should be two-thirds above the soil, and the pots should be plunged in a bed having a temperature of 80 degrees, with a house temperature of from 50 to 60 degrees. Shade should be given during brilliant sunshine, except when the bulbs are drying off, when they cannot have too much. No water should be given until the pots are well filled with roots, although the plunge bed must be kept moist, and hard-baked pots should be avoided. When the flower-scape is three inches in length the pots should be lifted from the plunging material and stood on the stage. After flowering, the dead blooms should be removed, but not the stem; replace the plants in the bed, and give a good coating of rich soil; water, and syringe freely. Insects are not usually troublesome, but mealy bug and thrips are the worst enemies, and, with good treatment they will be kept at bay.

Mr. Ker exhibited some plants carrying flowers of good substance, colour, and form; a bulb that had been started a few weeks was cut in two, showing the spike in its very early stage.

A good discussion followed, in which many other interesting points were brought out. Among the speakers were: Messrs. R. Todd, J. Stoney, E. Bache, G. Haigh, W. D. Skinner, —. Little, and R. G. Waterman. A cordial vote of thanks was tendered to Mr. Guttridge for presiding, and to Mr. Ker for his excellent paper.

Croydon Gardeners' Society.

Much interest was taken in a lecture on "Insect Friends and Foes," delivered before the Croydon Society at the Sunflower Temperance Hotel, by Mr. H. Withers, of South Croydon.

Mr. Withers divided this family into seven groups, and illustrations by diagram and lantern slides helped to explain each class to the audience. How much better one is able to cope with the minute depredators or encourage those which are useful in the garden by studying the structure and history of their mode of living was clearly exemplified. Often, the lecturer explained, little friends in the insect world are destroyed through ignorance of their usefulness. Amongst those to be encouraged are the ladybird whose larva feeds upon aphides, the golden-eyed fly, ants, and many of the ichneumon flies. The lecturer remarked how interesting it was to watch the larva of the lacewing fly at work holding the aphis with its jaws, and sucking the juices from the body.

In some respects it was unfortunate to the gardener that Nature had ordained more enemies in the insect world than friends, and means had to be found to eradicate many of these pests with the aid of fumigants and insecticides. It was in this way that many friends were destroyed. Unlike animals, insects had no lungs, but breathed through long tubes called tracheæ, running through the body and limbs, and in many instances ways had to be found for stopping these tubes, whilst others were destroyed by poisonous juices placed in their haunts.

It must not be forgotten, the lecturer said, that insects played a great part in the fertilisation of flowers. The principal amongst this class are the bees. Many flowers had so developed themselves as to favour the classes of insects that could help their fertilisation, as, for instance, the pea and bean flowers, delphiniums, etc.

When a vote of thanks was conveyed to him by the meeting, the hope was expressed that Mr. Withers would supplement his remarks with another evening's discourse at no distant date.

Mr. P. F. Bunyard had a few interesting exhibits, including a nest of the yellow fink, an insectivorous bird from South Africa; Mr. Gregory had mounted specimens of insects for the microscope, and of plants; Mr. Mills staged a fine specimen basket of Lachenalia Nelsoni, and Mr. A. Edwards an exceedingly well-grown Pteris tremula.

Weybridge Horticultural Society.

At the last monthly meeting the president, Mr. J. Lyle, presided over about sixty members. Mr. Lingwood, of the Egham Society, read an excellent paper on "The Culture of the Azalea." Several members asked the lecturer questions, which were met with ready answers. A splendid lot of exhibits were staged by the members, notably amaryllis, primulas, cyclamens, kales, and parsnips. Votes of thanks to the lecturer and president closed an instructive meeting.

National Chrysanthemum Society.

About forty-six members and friends of the National Chrysanthemum Society met at the Popular Café, Piccadilly, W., on the evening of Monday, February 24, under the presidency of Mr. R. Ballantine. The occasion was the fourth Market Show dinner, a function to which many of the market chrysanthemum growers come. An excellent dinner was served, and the tables were decorated with Framfield Pink chrysanthemums and daffodils.

The speeches were few in number, and laudably brief. The Chairman proposed "The King and Queen and Royal Family," and, after this had been honoured, "His Grace the Duke of Bedford," was toasted, and heartily thanked for his kindness in allowing the use of the Foreign Flower Market for the Market Chrysanthemum Show. The loss of Mr. Assbee was deplored, and of his successor, Mr. Frost, many kind things were said.

The presentation of prizes then followed, Mr. Philip Ladds receiving a silver cup, a gold medal, two large silver medals, and two small silver medals; Mr. Tulley and Mr. Weir were also present to receive their awards, but several prizewinners were unavoidably absent. The next item was the toast of the "National Chrysanthemum Society," proposed by Mr. Ballantine, who said the Market Show of 1907 was the finest yet held, and added that the N.C.S. continued to prosper. The response was in the hands of Mr. Thos. Bevan, chairman of the N.C.S. Committee. The other toasts were "The Chairman," proposed by Mr. Hawes; and Mr. D. Ingamells, the moving spirit of the Market Show, whose health was proposed by the Chairman; and "The Gardening Charities," proposed by Mr. Mackerchar, and responded to by Mr. G. J. Ingram.

A lengthy programme of music was provided, this extending to fifteen items, the artistes being Miss N. Beare, Miss Such, Mr. H. D. Porter, Mr. W. Bamforth, Mr. Laurence Harewood, Mr. Wilfred Stracey, Mr. Walter Fullerton, and Mr. Harry Briden, and all rendered their parts well.

Among those who were present we noted Mr. T. Bevan, Mr. E. Hawes, Mr. R. H. Witty, Mr. McKerchar, Mr. Caselton, Mr. W. Howe, Mr. Ingamells, Mr. G. J. Ingram, Mr. Eihle, Mr. J. W. Moorman, Mr. Prickett, Mr. Ladds, Mr. Curtis, Mr. Such, Mr. Tulley, etc.

Crawley Gardeners' Association.

According to the report presented to the annual meeting, which was held a few days since, the Crawley Gardeners' Association continues to make most satisfactory progress. The membership had increased from 175 to 193, the meetings had been well attended, and visits had been made to several noteworthy gardens. Among other gardens visited were those of Gatton Park, Kew, and Hampton Court. The financial statement showed a balance in hand of £12 13s. 2½d. Both report and financial statement were unanimously adopted, on the proposition of the chairman, Mr. T. H. Martin, who heartily congratulated the society on the successful results of the past year's work. The officers and members of committee were re-elected.

Reigate Gardeners' Association.

A meeting was held on February 18, Mr. W. P. Bound in the chair. Mr. H. G. Cox, secretary of the Reading Gardeners' Association, gave a most interesting and instructive lecture on "The History and Cultivation of Primula Sinensis." About sixty lantern slides were shown, many of which were coloured by hand, and a good number were done by colour photography, taken by the new autochrome process. Mr. Cox had a large number of fine primula flowers on view, and some plants in three-inch pots, each carrying a good head of bloom.

A first-class certificate was awarded to Mr. Herbert, gardener at Nutfield Priory, for a collection of apples, and to Mr. Barker, inside gardener of The Mount, Earlswood, for a specimen of Dendrobium Cooksoni; a second-class certificate was awarded Mr. Kemp for four primulas, and to Mr. Horsley for a dish of Tangerine oranges. Ten new members were elected.

Mr. Cox was accorded a very hearty vote of thanks.

A special meeting was held at Mutton's Hotel, Redhill, on February 22, Mr. W. P. Bound in the chair. Mr. N. E. Brown, of the Kew Herbarium, gave a most instructive lecture on "The Pronunciation of Plant Names." Mr. Brown handled his subject in a masterly manner, and his lecture was highly appreciated by the large audience. Many of the names were supplied by the members, and in this way many errors were corrected.

A very hearty vote of thanks was accorded Mr. Brown for his valuable lecture, which closed the meeting.

Beckenham Horticultural Society.

On Friday, February 15, Mr. J. R. Pocock, of College Nurseries, Bromley (the Rev. G. C. Griffiths presiding), gave a lecture on "Hardy and Rock Plants." After speaking at some length on the construction of rockwork, the way and time to plant, soils to use, etc., etc., the lecturer, having about a hundred specimens in pots in the body of the hall, took them individually, pointing out their types and varieties, their rarity or otherwise, ease of propagation, or vice versa, and their prices as governed by these things. He urged very firm planting indeed, and not to split up choice plants after midsummer, as to do so would probably end in loss during winter. The very best time to propagate, he said, was just as growth is commencing.

A hearty vote of thanks to Mr. Pocock and the rev. chairman closed the very instructive evening.

TRADE NOTE.

It is not often that tubers of the brilliant Flame Flower (Tropæolum speciosum) are offered to the public in quantity, so that the notice in the catalogue of Mr. H. N. Ellison, of West Bromwich, to the effect that he has a very large stock to offer at unusually low prices, is specially interesting. Now is the time to plant the tubers.

NEXT WEEK, March 7, will be issued

THE
SPRING NUMBER
OF THE
GARDENERS' MAGAZINE.

The Contents will include:—

SOME FAMOUS CORNISH GARDENS—
  Tremough, Rose Hill, Trelissick, and Penjerrick.
SWEET PEAS FOR EXHIBITION.
WINTER FLOWERING CARNATIONS FOR PRIVATE GARDENS.
DECIDUOUS CALANTHES.
MOON DAISIES.
THE CARE OF GARDEN TOOLS.
A GARDEN OF ANNUALS.
RECENT ADVANCES WITH LILACS.
LONG KEEPING APPLES.
GARDEN SEATS.
PYRAMIDAL IVY-LEAF PELARGONIUMS.
WEEPING STANDARD ROSES.
Etc., Etc.

With the number will be presented a
COLOURED PLATE
OF EARLY FLOWERING TULIPS.

Price **TWOPENCE**; by post, 2½d.

Offices: 148 & 149, Aldersgate Street, London.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

MELON CULTURE.—T. L. B., Otley: We cannot do better than refer you to our issue of February 15, where, on page 121, is an excellent article on melon culture by Mr. Jas. Mayne.

HARDY PERENNIALS.—M. S. G., Oxford: A very handy work dealing with the culture of hardy perennials, and giving the genera, species, varieties, and English names of the best to grow, is "Easily Grown Hardy Perennials," to be obtained post free for 5s. 6d. from The Gardeners' Magazine Office, 148 and 149, Aldersgate Street, E.C.

CELERIAC.—F. C. H., Malpas: Sow the seeds at the end of February or early in March in a box or pan, and place in a temperature of about 65 degrees—in fact, treat as for celery. Transfer the seedlings singly to sixty-sized pots when large enough. When established proceed to harden the plants, and subsequently plant them out about the last week in May. Choose a plot that was well manured and trenched during the winter, and set out the plants fifteen inches apart in rows eighteen inches apart. Plant firmly, and allow the plants to remain in the same relative position as regards the soil level as when they were in the pots. Abundant watering and liquid feeding are not necessary for celeriac, and in this respect the crops differ materially from celery. Firm soil and firm planting are essential to success.

MANURES FOR POTATOES.—A. B., Hambledon: In your case, and with such a soil to deal with, the best plan will be to apply superphosphate and sulphate of potash at planting time, using 3lb. of the former and 1½lb. of the latter per square rod. These should be mixed together and given at planting time, sprinkling them along the drills. Nitrate of soda, at the rate of 1lb. to the square rod, should be given when the potato shoots are a few inches above the ground, hoeing it in lightly, or applying it in showery weather. Basic slag should be given in the autumn, and it is of the greatest value on peaty or clayey soils in which there is a lack of lime. The other materials you mention we should not use for the purpose. The first named is better suited for plants in pots and for all cultures under glass, while the last named would not, we presume, be at all suitable for any but the purpose for which it is made.

SWEET PEAS.—A. S., Liskeard: The varieties that head the list in their respective colour classes in the National Sweet Pea Society's Classification of Sweet Peas for 1907, are as follows: White, Dorothy Eckford; crimson and scarlet, King Edward VII.; blush, Mrs. Hardcastle Sykes; cerise, Coccinea; rose and carmine, John Ingman; yellow and buff, Mrs. Collier; pink, Countess Spencer; orange shades, Helen Lewis; blue, Romolo Piazzani; violet and purple, Duke of Westminster; lavender, Lady Grizel Hamilton; mauve, Mrs. Walter Wright; magenta, George Gordon; red striped, America; purple-striped, Princess of Wales; maroon and bronze, Black Knight; picotee-edged, Dainty; fancies, Agnes Johnston; bicolors, Jeannie Gordon; and marbled, Helen Pierce.

GLOXINIAS.—D. G., Swanley: Place the tubers in small well-drained pots, in a mixture of equal parts loam, leaf-mould, and peat, with sufficient sand to render the whole porous. When potted the surface of the tuber should be on a level with the soil. A temperature of 60 deg. by night, rising to 65 or even 75 deg. by day with sun heat will be the most suitable. If the soil is comfortably moist at potting time then no water will be needed until growth has well commenced, but a humid atmosphere should be maintained by damping down the floors and by syringing between and around the pots. Overhead syringing is too risky for amateurs to practice, because unless it is done very lightly and carefully damping will result; after they have started into growth gloxinias should not be syringed overhead, as syringing induces flabby leafage. Gloxinias love plenty of light, and therefore they need only be shaded from bright sunshine. Heavy shading and excess of moisture produce weakly plants that cannot yield sturdy-stemmed, fine flowers. If leaves and flowers lack substance then the plants are of little value for conservatory or room decoration. When the young plants have made some progress they should be placed in larger pots in similar compost to that already advised.

SINGLE CHRYSANTHEMUMS.—N. N. A., Chesterfield: Cuttings can be rooted at any time from the beginning of January till March is well advanced, but amateurs should, as a rule, raise their stock from cuttings struck in February. This will give the plants plenty of time to grow to a full size, and they will have the advantage of an abundance of sunlight and a freer circulation of air from the time they are transferred from the cutting pots. The cuttings should be inserted several together in five-inch pots, and be placed in a frame in the corner of the greenhouse or other structure, where they can be kept close and shaded for a few days. When the cuttings are rooted they should be potted off singly, and put into three-inch pots. When these are well filled with roots, they should be transferred to six-inch pots, and, if rather large specimens are required, they should receive a further shift, this being into pots eight inches in diameter. As in the previous repotting, the shift should be given when the pots are well filled with roots, and before they have become pot-bound. In the preparation of the cutting pots a light sandy soil should be used, and this should be surfaced with silver sand. For the several repottings a compost, consisting of good turfy loam five parts, and well-rotted manure, two parts, will be the most suitable. From the time they are put into the three-inch pots until they are placed out of doors in May, they should have a position near the glass and a free circulation of air about them. When taken out of doors they should be given an open position, the pots be stood upon a bed of coal ashes and some ashes or other loose material be packed about them to check the evaporation of moisture. The growths should be stopped two or three times, the last stopping to be done by the middle of July. They will require rather liberal supplies of soot water and liquid manure when well rooted in their final pots.

SPOTTED DENDROBIUM LEAVES.—W. H. S., Chipping Sodbury: Mr. H. J. Chapman, to whom we submitted the specimens, writes: There can be no doubt that the pseudo-bulbs and leaves sent are badly affected by the dreaded "Black Spot." Orchids, principally those of the Eastern group, such as dendrobiums, calanthes, phaius, phalænopsis, and some of the vandas, are particularly subject to these undesirable disfigurements. I have also seen Cœlogyne cristata badly affected on two or three occasions. At one time we suffered a great deal from spot, and I submitted specimens to various people for scientific investigation, but none were able to identify any fungoid growth to account for the spotting or bacteria which might be likely to cause the trouble. I came to the conclusion that our methods of culture might be the cause, and am now satisfied that this was to a great extent correct. Where one has a mixed collection of plants growing together under practically the same conditions, success may attend our efforts at first, especially so if we are dealing with imported orchids, for I have seen freshly imported orchids growing satisfactorily under the most adverse conditions for a season. W. H. S.'s complaint is precisely the same as that of others; the difficulty rarely commences until the pseudo-bulbs and growths are matured or nearly so. Some two or three years ago I gave my experience of a housefull of calanthes in the columns of The Gardeners' Magazine, and later, in the Weekly Calendar Notes, I stated the successful methods that had been practised, and I am perfectly satisfied with the success that has since followed the treatment I then advised. The surroundings under which the plants grow naturally are very definite, wet or dry seasons. Such conditions are very difficult to provide artificially. Where we make mistakes is generally at the completion of growth. I saw an instance last autumn where a stove containing orchids principally was damped down, closed, and the blinds drawn up to permit the sun to reach the plants. The temperature at the time I entered was 95 degrees, with the sun full on the glass; this practice, with stove plants, is quite familiar to gardeners. I do not think this would have caused any harm had the practice been applied in the months of June or July, when the plants were in full growth, but as it was in the middle of September, when the plants had practically matured their growths, I came to the conclusion that if there was no trouble it would be rather strange. I am not sure that this was actually the cause, but I was asked to come and see the plants a few weeks later, when many of them were showing small white spots on the foliage and indentations on the pseudo-bulbs, which all ultimately developed into black spot of the most serious description I have ever seen. These are conditions to avoid. When the pseudo-bulbs of a calanthe or dendrobium have reached maturity, atmospheric moisture should be reduced, and while the temperature may not be materially lowered for a few weeks, the top ventilators should be brought into use to prevent a stag-

BY SPECIAL APPOINTMENT TO HIS MAJESTY KING EDWARD VII.

GREEN'S PATENT LAWN MOWERS.

The First, Foremost, and Best in the World. Hundreds of Thousands are in use. Established nearly a Century.

CLAY & SON, Manure Manufacturers and Bone Crushers, STRATFORD, LONDON, E.

nant atmosphere. If we can provide conditions practically similar to that usually given to a house of melons when ripening. I am quite certain this would be the correct treatment for all the warm-house orchids that are liable to this dreaded disfigurement. The resting of such species as Dendrobium Findlayanum (which have pseudo-bulbs and growths of a sappy nature) in a temperature of 50 degrees, would not do, as this would be 5 to 10 degrees too low. With such a low temperature, and the atmosphere charged with moisture, the development of spotting would be considerably assisted. The whole of the hybrids from D. Findlayanum should also be rested in a temperature of about 60 degrees.

NAMES OF PLANTS.

E. P., Reading.—1, Acacia dealbata; 2, Iris sindjarensis; 3, Jasminum nudiflorum.

F. E., Mitcham.—1, Woodwardia radicans; 2, Virburnum Tinus; 3, Hibbertea dentata; 4, a good form of Clivia miniata.

M. H. B., St. Neots.—1, Shortia galacifolia; 2, Libocedrus decurrens; 3, Abies Pinsapo; 4, Cupressus macrocarpa lutea.

R. N. J., Huddersfield.—1, Cattleya Trianæ, a fairly good variety; 2, probably Rhynchospermum jasminoides; 3, Calceolaria Burbidgei; 4, Eucharis candida; 5, Aralia Chabrieri.
